1. Management Summary

This document has been produced by the consortium of the European Project FP7-247708 Sustainable Urban Development Planner for Climate Change Adaptation (SUDPLAN). It is the companion report to the second deliverable of T3.3 Product Implementation which represents the software developed on the basis of the results of T3.2 Product Prototyping and T3.1 Requirements Specification. It is an update of the first report (D3.2.1) and provides an overview of the distinct building blocks of the SUDPLAN platform and briefly explains their architecture and reports on the developments performed during the second product implementation phase.

1.1. Purpose of this Document

This document is a brief report to accompany the software developed in WP3 (Scenario Management System) in the second year of the SUDPLAN project bundled into D3.2.2 Product Implementation V2. The software described here constitutes the components that make up one of the core results of SUDPLAN - the Scenario Management System. In contrast to D3.3.2 Scenario Management System V2 the developed software components are not presented as an integrated solution but rather as individual building blocks. The results of D3.2.2 combined with the results of D3.3.2 are the basis for the second validation cycle performed by the pilot applications.

1.2. Intended Audience

This document targets all SUDPLAN partners.

1.3. Summary and Structure of the Document

This document is the companion report to the software deliverable D3.2.2 Product Implementation V2 and is divided into three main parts.

The first part is an introductory chapter that explains the role of the partners involved in the work performed, gives an overview on the overall development process, and explains the basic purpose of the Scenario Management System. Furthermore, it highlights the relationship of the software deliverable to other tasks and deliverables of WP3 and gives a rationale for the choices of technologies and products used to implement the Scenario Management System Building Blocks.

The second part of the report gives a brief outlook on the overall architecture of the integrated SMS presented in D3.3.2 Scenario Management System V2.

The third part of this document provides detailed information on the following for each distinct Building Block of the Scenario Management System:

- The general purpose of the components of the Building Blocks and their relationships to the Scenario Management System requirements specified in D3.1.2 Requirement Specification V2.
- The software and tools (such as APIs, products) used for the implementation of the components, including a description of their architecture and provided functionalities.

- The incremental results of the second product implementation phase including an overview of realised functionalities.

- A brief outlook on the third product implementation phase

- A summary of the key features of the current release and references to relevant software repositories necessary to access the results of the development effort of the first project year.

The document closes with conclusions that can be used to gain an overview without reading the entire document.

2. Introduction

The main objective of WP3 work is to develop an ‘easy-to-use web-based planning, prediction, decision support and training tool, for the use in an urban context, based on a what-if scenario execution environment’ (DoW).

The development work performed to provide the software was divided according to the WP3 partner’s field of development expertise.

The current implementation results which will be integrated into the Scenario Management System are classified as basic scenario management core functionality, model integration, and visualisation. With respect to the WP3 partner’s responsibilities, the Scenario Management System can be divided into the three distinct Building Blocks **SMS Framework**, **Model as a Service Integration**, and **Advanced Visualisation**. These Building Blocks are further explained in Chapter 4 *Scenario Management System Building Blocks*.

The general software development process in SUDPLAN follows a three iteration spiral development approach, in which we have now have reached the end of the second cycle.
Figure 3: SUDPLAN Spiral Approach

The incremental results of the second cycle as well as a brief outlook on the development plans for the third year are given at the end of each Building Block chapter.
2.1. Tasks and Documents involved

As can be seen in Figure 4: Dependencies in the Development Process, the implementation of the SMS Building Blocks has been influenced by several activities in the overall project.

In the first year of SUDPLAN the developments were mainly driven by the Product Conceptualisation (T2.2), the Product Prototyping (T3.2), and the Requirements Specification (T3.1) Tasks. The requirements and user needs analysis, as performed in the course of T3.1, are further explained in the D3.1.2 - Requirement Specification. In short, they consisted of intense interview and discussion sessions with the pilot users and the study and analysis of the DoW, relevant projects, literature and other sources of requirements for the SMS. While T3.1 provided major input to the Pilot Definition Plans (D5.1.2 – D8.1.2) and T2.2 and T3.3, its immediate result is the deliverable D3.1.2. In addition, mockup activities were performed to be able to capture the user vision for the SUDPLAN product. Therefore, numerous mockups were produced on the basis of the requirements identified in T3.1 and were discussed with the pilot users.

In the second year, first validation results, an enhanced requirements document and more and enhanced mockups have been available. The refined and consolidated SMS requirements documented in D3.1.2, together with the mockups specified in T2.2 and T3.2, have been used by the developers of the SMS building blocks to identify and implement the concrete SMS functionalities. The immediate results of the WP3 development process (T3.3 and T3.4) are a set of distinct components, presented as SMS Building Blocks in this document, and the integrated...
SMS itself, presented in the document *D3.3.2 Scenario Management System V2 – Companion Report*.

In the second year of SUDPLAN, the developments have not been influenced solely by refined requirements (D3.1.2) and ongoing mockup activities but also by the outcome of the *Product Validation and Evaluation Task* (T2.3) as shown in *Figure 5: Second Year Development*. Thus, the findings of the currently available Validation and Evaluation Report (D2.2.1) have been taken into account during further development and integration activities.

![Figure 5: Second Year Development](image)

In addition to the recommendations made in the first *Validation and Evaluation Report (D2.2.1)*, the early results of the second Validation and Evaluation Phase, which is based on the refined *Validation Plan (D2.1)* have been considered in the second year developments.

### 2.2. Choice of Core Technologies

The choice of technologies, products and software components for the implementation of the SUDPLAN product is driven by the requirement to provide a sophisticated yet simple to use planning tool by the end of the project. The goal of the project is to develop a mature software solution that can be adapted to the needs of any European city with minimal effort, rather than a proof-of-concept implementation that serves as the basis for further developments. In order to reach this goal it is necessary to select software components that already provide the infrastructure and a certain set of core functionality on which the SUDPLAN product can be built. Furthermore, the SUDPLAN product has to adhere to certain fundamental expectations expressed in the DoW, which imposes certain technical requirements on the type of software components that can be selected for the implementation. Moreover, the SUDPLAN partners involved in the implementation of the SMS Building Blocks must be able to extend, configure and adapt the selected software components in consideration of their personal expertise, the planned resources and the given time frame.

The core features of the Building Blocks including their relationship to the platform requirements specified in *D3.1.2 - Requirement Specification V2*, are described in the sections *4.1 Scenario Management System Framework, 4.2 Model as a Service Integration* and *4.3 Advanced Visualisation*, respectively.
2.2.1 Scenario Management

The aforementioned considerations have already been taken into account during the preparation of the project, and have led to the plan to use the cids product of cismet as the basis for the SMS Framework. Cids ([http://www.cismet.de/en/cidsfacts.pdf](http://www.cismet.de/en/cidsfacts.pdf)) is an open source toolkit for the management and integration of complex, heterogeneous, multi-domain, multi-use data of both a temporal and spatial nature. It has been used in the ICT context, including FP4 and FP5 projects. cismet, as developer of cids, has the necessary knowledge to adapt it to SUDPLAN needs, thus developing SUPDPLAN specific extensions and providing integration and training support for the rest of the consortium.

2.2.2 Model as a Service Integration

The implementation of SOS and SPS related software is based on the Time Series Toolbox (TS-Toolbox) API from AIT. The TS-Toolbox API provides the means to conveniently deal with arbitrary time series.

We decided to use the TS-Toolbox because it represents a good starting point to implement dedicated services to wrap the various existing models needed in SUDPLAN and to establish the basis for the integration of new local models through standardised service interfaces. In the SANY project, we found that the use of existing SOS and SPS implementations, e.g. from 52° North Initiative [SOS52N, 2011] is not feasible as they are complete systems, and they are not built to act just as an interface implementation to wrap existing models or data bases. Many parts of the TS-ToolBox, especially on the client side, can be used or adapted to suit SUDPLAN needs.

2.2.3 Advanced Visualisation

It was decided to use the freely available World Wind Java SDK component as the basis for further developments of the Advanced Visualisation Component. After the integration of the World Wind SDK it was thus possible to focus only on the visualisation and animation of 3D results and predictions, in particular using the 3D landscape.

The World Wind SDK is a free and open source Java-API for a virtual globe released under the NASA Open Source Agreement (NOSA). The framework provides a powerful platform for giving the SMS the means to express, manipulate and analyse data of interest. World Wind provides many features for displaying as well as interacting with geographic data and representing a wide range of geometric objects. Moreover, extending the API is simple and easy to do. World Wind features include:

- Open-source, high-performance 3D Virtual globe API and SDK
- Open-standard interfaces to GIS services and databases
- Display high-resolution imagery, terrain, and geographic information from any open-standard public or private source
- Huge collection of high-resolution imagery and terrain from NASA servers
- Supports Coordinate System: Lat/Lon, UTM, MGRS
• Supports of GeoTIFF, JPG, PNG, and JPEG2000
• Supports standard GIS formats: Shape file, KML, GML, GeoJSON
• Different Navigation Modes are being supported
• Supports visualization for stereoscopic displays

Organizations across the world use and support the on-going development of World Wind to monitor weather patterns, and visualize cities and terrain. With World Wind taking care of the basic concepts of visualizing geographic data on a virtual globe, we are now able to focus on solving the domain specific problems and to focus mostly on the visualisation and animation of 3D results and predictions, in particular using the 3D landscape.
3. **Scenario Management System Overview**

The Scenario Management System is the platform on which any SUDPLAN Application (or SUDPLAN System) is built. It consists of the three distinct Building Blocks described in Chapter 4 - *Scenario Management System Building Blocks* of this document and can be seen as a generic integration platform that will be able to facilitate climate change induced urban development planning in any city in Europe. The goal to provide a universal, flexible and adaptable planning tool is supported by the separation of the SUDPLAN System into several architectural layers as shown in *Figure 6: SUDPLAN Layered Architecture*.

![SUDPLAN Layered Architecture Diagram](image)

The top-level layer, the SUDPLAN Application itself, is the result of an extension, customisation and configuration of the underlying SMS. The SMS comes with everything needed to provide common scenario management tasks including data integration, model management and execution, workflow management, basic and advanced visualisation, and comparison of various temporal and spatial data sets, etc. It therefore relies upon standard services for data access and model management and thus greatly facilitates the task of integrating new models and data sources. Consequently, the same mechanisms used for interfacing the SUDPLAN Common Services with the SMS can be used for local model and data source integration. As shown in *Figure 7: OGC Services Integration*, several services specified by the Open Geospatial Consortium (OGC) are supported by the SMS: Sensor Planning Service (SPS), Sensor Observation Service (SOS), Web Map Service (WMS) and Web Feature Service (WFS). Their usage is further explained in Chapters 4.1 - *Scenario Management System Framework* and 4.2 - *Model as a Service* Integration.
It is also possible to develop a custom model integration solution with respect to particular user requirements. The SMS Framework allows both standard and custom integration without the need to change the SMS itself. For this purpose, the SMS Framework exposes an API that enables the developers of a SUDPLAN Application to extend the SMS with their specific functionalities. The four pilot applications of the SUDPLAN project therefore validate not only the general approach of the SMS but also its adaptability/transferability and thus its applicability to any city in Europe.
4. **Scenario Management System Building Blocks**

In this chapter, the three Building Blocks of the Scenario Management System and the incremental results of the second product implementation phase are presented in detail. These are described in the following subsections:

- Scenario Management System Framework
- Model as a Service Integration
- Advanced Visualisation Component

Each subsection starts with a short introduction of the role of the component in SUDPLAN and lists the expected properties and functionalities in relation to SUDPLAN requirements. It continues with the description of the chosen software components, presents their architecture, and briefly explains by which means it realises the anticipated functionalities. It further provides documentation of the developments carried out in the second year, specifically referring to new functionalities implemented, and presents a brief outlook on the development plans for the third year. Finally, it gives a summary of the achievements of the second year and points to the software repository that contains the actual results.

4.1. **Scenario Management System Framework**

The Scenario Management System Framework (GUI shown in Figure 8: SUDPLAN SMS GUI) is the central component providing common SMS and integration functionality. Together with the Building Blocks for the integration of models through standardized services and for advanced visualisation capabilities it provides the basis for pilot specific implementations and the necessary workflows to support the use of models as a basis for decision making.

![Figure 8: SUDPLAN SMS GUI](image)
The core functionalities provided by the SMS Framework include, for example, support for the management of models, i.e. model execution, result storage, parameterisation and basic model result visualisation (such as 1D time series, and 2D maps).

The complete set of functionalities that has been provided by the SMS Framework as well as general properties of the anticipated scenario management system can be derived from the requirements specified in D3.1.2 - Requirement Specification V2. The SMS Framework must not be confused with the integrated Scenario Management System as described in Chapter 3 - Scenario Management System Overview. Therefore, functionalities intended to be covered by the Common Services, pilot specific applications, the Advanced Visualisation Building Block, and the Model as a Service Building Block, are considered in the SMS Framework only when it directly contributes to their implementation.

The general properties of the SMS Framework as well as the overall Scenario Management System are related mostly to technical and high level requirements stemming from the DoW, ICT expectations, and best practices from various sources. In summary, the SMS Framework must

- be scalable, open and reliable
- be based on open standards, and make use of open standards
- be based on open source products, and be itself an open source product
- be based on technologies making use of the World Wide Web
- provide a generic infrastructure independent of a particular domain
- provide integration with SOA-based infrastructures and standards-based services
- provide security and access control mechanisms
- offer user-friendly graphical interfaces to improve usability

The core functionalities to be supported by the SMS Framework can be derived from the overall objectives of the project as well as specific requirements expressed by the different users of the SMS and requirements from developers that perform configuration, management, extension and integration tasks. In summary, the perceived functionalities of the SMS Framework are to

- provide functionalities for city management, planning and decision support in the context of climate change adaptation
- provide applications and tools for the management of scenarios
- provide integration, management, calibration, and configuration facilities for models
- provide automation of tasks like model runs, analysis and reporting
- allow the discovery of relevant sources
- provide spatio-temporal visualization of disparate information
- provide visualisation and comparison of model run results
- support sharing and publishing of information (e.g. model results, reports)
- support the management of various and disparate information sources

Each requirement can be further broken down into more detailed and concrete functionalities such that all relevant requirements defined in D3.1.2 - Requirement Specification V2 will be taken into account by the developers.
4.1.1 Components and APIs used

As already indicated in 2.2 - Choice of Core Technologies, SMS development efforts are based on the open source cids\(^1\) geo-integration platform. cids is based on a 15 year development effort and was developed by the Environmental Informatics Group (EIG\(^2\)). It was used in several projects including FP4 and FP5 projects. In 2001, it was turned over to cismet GmbH. All cids components are written in Java and thus are platform independent and web-enabled.

The cids product suite consists of a set of services, applications, software components, management tools, development tools, and application programming interfaces (APIs) for the management, integration, and development of heterogeneous information systems with a special focus on interactive geo-spatial systems. It provides a distributed integration platform, which is particularly useful for workflows that need a combination of information and processes from different source systems such as GIS systems, relational databases, and simulation models. In this way it already provides and supports a number of functionalities of the anticipated SUDPLAN SMS, including user management and access control, search and discovery of relevant information and advanced interactive 2D visualisation (OGC WMS and WFS clients). The developments carried out in the first and the second year to provide support for additional SMS-specific functionalities like scenario management and result visualisation and comparison are described in section 4.1.2 - First Year Development and 4.1.3 - Second Year Development.

![Figure 9: SMS Framework Client-Server Architecture](image)

**Figure 9: SMS Framework Client-Server Architecture** shows that the SMS Framework is based on a client-server architecture in which an arbitrary number of client instances and server components co-exist in a service network, thus ensuring scalability and reliability. The components shown in Figure 11 are explained in detail in the following sections.

---

\(^1\) http://www.cismet.de/en/products.html

\(^2\) http://www.enviroinformatics.net
The main building blocks of the SMS Framework are the Navigator (client), the Kernel, and a set of system management tools. The building blocks and the components are shown in Figure 10: SMS Framework Building Blocks.

The **Kernel** represents a network of distributed services and consists of the following four components:

- **Integration Base**
  The Integration Base is a distributed meta database which consists of a generic meta data model placed in a relational DBMS (Data Base Management System). Figure 11: Generic Meta Data Model of the Integration Base shows an excerpt of generic meta data model. It is the basis for a concrete information system and is able to describe arbitrary objects (real-world objects, services, models, geographical features, other information systems, etc.), their attributes (e.g. geographical location) and relationships by means of so-called meta classes and objects. The generic meta data model also supports a dynamic navigational catalogue structure, users, groups and permissions, and many other properties.
**Domain Server**
The Domain Server is the interface to an Integration Base and is responsible for the translation of the generic meta data structure into concrete meta objects and classes, thereby also supporting the creation and updating of meta data. It is also responsible for the construction of the dynamic catalogue structure at runtime.

**Registry Server**
The Registry Server is responsible for the resolution of distributed user privileges needed for the enforcement of access rights, the resolution of the distributed catalogue structure needed for the navigation, and the coordination of the distributed search. It also provides service infrastructure related functionalities like server name resolution, network monitoring, status information, etc.

**Broker**
The Broker is the interface to the clients and hides the distribution aspects of the system. It acts like a proxy and delegates client requests to the appropriate Domain Servers.

The **Navigator**, shown as a customized version in Figure 8: SUDPLAN SMS GUI, is the default client for user interactions with the system. It offers a uniform, user-specific view of the integrated information systems and is particularly useful for cross-system search and retrieval in space, time, and textual content. It can also be used to manage the information in the network. In SUDPLAN it will be used as the management client for OGC compliant data access and model execution services, which are described as customised information classes in the underlying meta data model, thus offering common scenario management functionalities for the various users of the system. The Navigator features a plug-in mechanism that allows the pilots to develop custom extensions in order to support workflows for their specific end user tasks. The Navigator provides the following core functionalities through dedicated GUI components:
• **Catalogue**
  The Catalogue presents a tree for navigation of the distributed catalogue and provides basic information about objects (Figure 12: Catalogue Attribute View). It supports caching of the dynamically constructed catalogue structure which can be distributed among several Domain Server and Integration Base instances. Furthermore, it provides functions to manage the catalogue structure as well as meta data objects (Figure 13: Catalogue Node and Object Management).

![Figure 12: Catalogue Attribute View](image1)

![Figure 13: Catalogue Node and Object Management](image2)

• **Search**
  There is a highly customisable interface to the dynamic search capabilities of the Kernel, which takes a combination of different meta object attributes into account to provide thematic search to end users. It also features sophisticated geospatial search capabilities and direct interaction with the Map Component.
• **Renderer**

Renderers are used to provide thematic, context and user dependent views on certain topics. The Navigator is equipped with a set of default Renderers for a variety of different object types and supports the integration of a customised Renderer on a per-object class basis. *Figure 14: Custom Rainfall Render as Client for OGC SOS* shows a custom Renderer that communicates with a Sensor Observation Service (see also 4.2 - *Model as a Service Integration*).

![Figure 14: Custom Rainfall Render as Client for OGC SOS](image)

• **Editors**

Editors are used to manipulate meta objects in a uniform manner, such as scheduled model runs as shown in *Figure 15: Default Attribute Editor*. As already mentioned, meta objects can represent arbitrary physical or virtual objects from simple documents over geographical features to complex workflows. In addition to automatically generated editors, which provide attribute based editing functionality, custom editors are also supported. Custom Editors can be used in SUDPLAN, for example, to provide advanced functionalities for the common configuration of models or to support pilot specific tasks.
Figure 15: Default Attribute Editor

- **Map Component**
  The Map Component shown in *Figure 16: Map Component (cismap)* is based on cismap, a highly sophisticated 2D map viewer for geodata services such as Web Map Services (WMS) and Web Feature Services (WFS) which comply with the standards of the Open Geospatial Consortium (OGC). Since cismap supports both powerful visualisation and editing functionalities for geospatial information (including arbitrary geolocated meta objects), it can support SUDPLAN end users during configuration, management and decision and planning tasks. Some of the main features of cismap are:

  - asynchronous WMS and WFS requests to load several WMS layers in parallel
  - dynamic addition of services, including drag and drop of the server URL
  - a powerful and easy to use geometry editor for the manipulation of geo-data
  - complete integration with cismap and support for the visualisation and manipulation of meta objects
  - a customisable user interface and the ability to save the layout on a per-user basis
  - the representation of geographical features on the map as complex widgets
  - customisable print and report generation facilities
The cids product suite provides, in addition to the client and server components described in the previous sections, a set of System Management Tools. They support system managers during the installation and maintenance of the SUDPLAN applications as well as modellers during the integration and configuration of mathematical models to be used within SUDPLAN applications. They can also be used to carry out general system administration tasks like user management. The System Management Tools include the following.

- **ABF**
  
  ABF, which stands for “Administrators’ Best Friend,” is a powerful front-end for the configuration of the meta data base. It can be used to define new meta classes and their attributes, relationships, dynamic catalogue structures and so on.
• **Server Console**  
The Server Console is used to monitor and control a server component or a whole service network.

• **JPresso**  
JPresso is a powerful ETL-Tool (Extraction, Transformation and Load Tool) for the integration of heterogeneous data-sources. It supports visual mappings that describe the connection between data-sources and the cids Integration Base.
The SMS Framework, based on cids components and tools described in this chapter, already fulfils most of the technical requirements that demand a generic infrastructure, open source components, web-based technologies, user-friendly graphical interfaces, security and access control mechanisms, and scalability. It represents a sound basis for the implementation of the SUDPLAN SMS core functionalities like scenario management, resource discovery, sharing and publishing of information, automation of tasks, and so on. The steps taken to use cids as a basis for the SUDPLAN SMS are described in the next sections.

4.1.2 First Year Development

The SUDPLAN SMS based on the cids platform described in the previous section has not only been deployed and configured to suit the needs of SUDPLAN, but the cids platform itself has also been extended to support the particular needs of data providers, data clients, and system integrators.

The first major task undertaken to support the SUDPLAN specific requirements was the extension of cids by a generic model management concept to support all aspects of model integration and management. The model management concept encapsulates model specific properties and provides user specific interfaces for the visualisation and manipulation of model input and output data. The information model of the model management concept shown in Figure 20: Model Management Information Model is flexible and adaptable such that it supports both SUDPLAN Common Services as well as arbitrary local models of the pilots or any other city applications.
The different entities of the Model Management information model shown in the diagram above are

- **Model Entity**, which defines the general properties of a model and is associated with Manager Entities.

- **Manager Entity**, which defines the model-specific implementations and their type, for example Java, Groovy, BPEL, etc.

- **ModelInput Entity**, which encapsulates the model input data and is associated with a Run Entity.
• **ModelOutput Entity**, which encapsulates the model output data and is also associated with a Run Entity.

• **Run Entity**, which defines information needed for the execution of the model and is associated through the ModelInput and ModelOutput Entities with the input/output data of the model.

Due to the generic nature of the cids system, no changes to the Kernel or the server components are required to support the Model Management information model. Therefore, the
second major task completed in V1 was the extension of the client (Navigator) to provide convenient user interfaces for model integration and management. The class diagram in Figure 26 shows an excerpt (interfaces and base classes only) of the Navigator extensions realised in V1.

![Class Diagram](image)

**Figure 26: Model Management Navigator Extensions**

The various Renderer classes refer to the custom Renderer concept presented in 4.1.1 - Components and APIs used. They map directly to the different Model Management Entities (Figure 27: Custom Model Management Renderer Implementation) and provide support for visualisation of the model configuration, input/output data, etc.

![Renderer Implementation](image)

**Figure 27: Custom Model Management Renderer Implementation**

*Figure 28: RunRenderer GUI shows the user interface of a custom RunRenderer implementation that displays the model execution status an of air quality downscaling run*
performed by the corresponding Common Service. It includes references to the model results and parameterisation (input/output data) which can be visualised by the associated ModelInputRenderer, ModelOutputRenderer, or FeatureRenderer. For reasons of clarity, the FeatureRenderer is not shown in the class diagrams above. In short, a FeatureRenderer is used when data have to be visualised in the map.

In V1, the RunRenderer supports basic model management and asynchronous model execution, providing the possibility to initiate several model runs in parallel. Access to the Common Services is realised with the help of the Model as a Service Integration which provides a standardised OGC SPS (Sensor Planning Service) interface for model execution.

![Figure 28: RunRenderer GUI Implementation](image)

Access to model input/output data can be achieved through SOS (Sensor Observation Service), WMS (Web Map Service) and WFS (Web Feature Service) interfaces. SOS is commonly used when 2D data are to be displayed as a graph or table. WFS and WMS can be used when the data have to be shown in the map. An example of a custom ModelInputRenderer that retrieves model input time series from a SOS and visualises it as 2D graph was shown in Figure 14: Custom Rainfall Render as Client for OGC SOS.

![Figure 29: Interactive FeatureRenderer](image)

Figure 29: Interactive FeatureRenderer shows a FeatureRenderer that visualises model input data (local Stockholm emission data). Retrieving data from a WFS and showing them in the map is a common feature of cismap. The feature implemented in the SUDPLAN V1 enhances interactivity through custom actions which can be performed on the individual features. In this case the feature representing the local emission data supports an action to initiate air quality downscaling.
The air quality downscaling action is associated with a model specific configuration wizard as shown in Figure 30: Air Quality Downscaling Wizard below.
Upon complete execution of the wizard a new model run is started, which can be monitored with the help of a RunRenderer already shown in Figure 28: RunRenderer GUI. Once the model run is finished, the output data can be retrieved and visualised. Figure 31: Visualisation of Model Output illustrates the possibility visualising model output data as a 1D time series, a feature which was also implemented in V1. The downscaled rainfall data produced by the corresponding Common Service in this example are managed by the SMS and thus can also be used as input data for custom local models.

![Downscaling results of (Rainfall Downscaling Run)](image)

Figure 31: Visualisation of Model Output (Time Series)

There is also the possibility of visualising model results in the map while taking temporal aspects into account. SUDPLAN is required to visualise changes over time in the map, but geographic features retrieved from WFS or raster image layers retrieved from WMS are static objects and WFS and WMS clients do not in general support temporal representation. Therefore, in V1 a new type of FeatureRenderer was developed that is able to interactively change the feature shown depending on the selected point in time. In the example shown in Figure 32: Interactive TimeseriesFeatureRenderer, ozone (O₃) concentration over a period of 100 years can be seen in 10 year intervals.
4.1.3 Second Year Development

Besides the general improvements and enhancements of V1 features like the development of a Download manager, the enhancement of the SMS catalogue (soft refresh), IDF visualisation support, the integration of the new, World Wind based 3D component, the developments in the second year concentrated on the stable integration of Common Services (Pan-European and Rainfall in particular), the integration of local models (pilot specific), and local data (e.g. time series) and the support of the integration of common service downscaling results into local model runs, with the help of the Scenario Management System. The foreseen integration of the Hydrology CS was moved to V3, however interactive and collaborative preparatory work of WP3 and WP4 has prepared the ground for an easy integration in Y3 including the basic downscaled data, interface specifications and a first back-end implementation (Java-API) that needs to be wrapped by a set of OGC services to complete the work. Regarding the SMS, additional emphasis has been put on the enhancement of time series visualisation and comparison features and enhanced asynchronous model control. Both aspects are described in more detail in the following sections.

4.1.3.1 Time Series Visualisation and Comparison Framework

It is obvious that most of the data available in SUDPLAN consist of time series as they deal with environmental data that are measured or calculated for certain points in time. The objective of this work is to develop a component to visualise and compare these time series.

The component is designed as a highly flexible and extensible framework that abstracts and hides visualisation dependent tasks, and offers uniform interfaces for the integration and access of the visualisation in the SUDPLAN user interface. This permits an easy integration of different visualisations for time series depending on their individual visualisation requirements (scalar, vector, gridded). The use of established software design patterns ensures easy access to and re-use of the framework.
The time-series visualisation component has to support the SUDPLAN users at their decision tasks. This requires the visualisation to be interactive and to support the user in the exploration of the processes that are represented by the time series. Besides multiple interaction techniques, particular emphasis is put on the comparison of multiple time series. In fact, SUDPLAN users need to compare results of various planning alternatives. The comparison abilities are extended by providing various operations that can be executed on time series.

![Image of Time Series Visualisation](image.png)

**Figure 33: SMS Using the Time Series Visualisation and Comparison Framework**

The basic idea of the new component is to support the user in the visual exploration of time series and the underlying processes. The component has to handle two different types of time series. Simple time series, such as temperature measured over a period of time and time series of grids. Time series of grids contain multiple data values (the grid) combined with a spatial reference for each time value. The visualisation of time series of 2D grids differs from regular 1D time series and thus demands dedicated visualisation methods. At this point it is not clear how multiple time series of grids should be visualised in SUDPLAN to gain an intuitive and comparative visualisation. Therefore we will concentrate on the visualisation of simple time series. However, due to the requirement of 2D grid time series visualisation, the component needs to be designed independent of the visualisation approach, which allows it to extend the component with a visualisation for time series of grids.

For simple time series the most frequent task is the display of the time series in different resolutions. This means that the user has a need to get very detailed views of time series as well as overviews which emphasize long term trends. The comparison of time series is also another important user task. As a consequence, the visualisation must display multiple time series
simultaneously, in single or multiple graphs. Another feature requested by the end users is the ability to execute operations on time series, for instance computing the difference or average of two time series. In any case, to facilitate comparison of time series, interaction with the charts is mandatory. Making it possible to scroll the data over time, zooming in or out the data, showing detailed information of points of interest or changing the chart type increases the visual exploration experience significantly and is needed by the SUDPLAN users.

The possibility to zoom in and out the data leads to another more technical issue. SUDPLAN users generally handle time series with a huge amount of data because of high resolution over long term periods. Even the first prototype of the SMS contained time series up to 200MB of raw data. SUDPLAN is designed in a loosely coupled and service oriented architecture and therefore these data must be first transferred before they can be visualised. Moreover, it must be possible to dynamically load and cache data dependant on the area of interest and the chosen granularity.

4.1.3.1.1. Basic Chart Visualisation API

There are already charting solutions for Java. They all offer the possibility to create various types of charts such as point, bar and line charts and are therefore a good basis for creating a component for time series visualisation.

The following Java charting APIs have been examined with regard to their ability for time series visualisation and comparison and their ability for interaction.

ChartFX\(^1\) is a commercial API for creating charts. It is the only API found so far that has built-in functionality for scrolling the dataset over the x-axis. It also has the largest number of chart types available. But due to the fact that SUDPLAN is developed as an open source project the charting API has to be available under open source license, which is not the case for ChartFX.

The Java Chart Construction Kit (JCCKit\(^2\)) is a very small and flexible framework and is especially designed for scientific charts and plots. It is very effective for dynamic and real-time charts, in which it is necessary to reload the data permanently, but the interaction possibilities with the charts are very limited and the API is not well documented.

OpenChart\(^3\) is another open source Java charting API. The functionality is similar to the JCCKit. The documentation of the API is just made up of the Javadocs and a very limited set of developer tutorials. Furthermore the built-in interaction functionality is very limited e.g. OpenChart2 does not even directly support the export of charts to image files.

The most suitable API is JFreeChart\(^4\). It is the most popular Java Charting API and is developed under GNU LGPL\(^5\). It is especially designed for the use in Java Swing and has a large set of different chart types. Charts created with JFreeChart provide the ability to zoom in and out of the data, dynamically add data points, and add or remove complete time series. Additionally JFreeChart comes with an event handling system similar to Swing that makes it possible to react

---

\(^1\) http://www.softwarefx.com/SFXJavaProducts/CFXforJava/
\(^2\) http://jcckit.sourceforge.net/
\(^3\) http://freecode.com/projects/openchart2
\(^4\) http://www.jfree.org/jfreechart/
\(^5\) http://www.opensource.org/licenses/lgpl-license
to users’ input (such as mouse clicks), which is used to generate a popup menu that provides the user further functionality. The API is well documented and a very extensive Developer Guide with many code examples is available. Furthermore, a forum on the project website exists, which can be used to get help from other JFreeChart users and the developer team. Although JFreeChart does not support all necessary features out of the box, it is possible to extend the API according to our needs.

SUDPLAN users need to compare time series with different variables in one chart, e.g. temperature and ozone. This means that the chart has to provide different scales and labels on the axis. JFreeChart supports line charts with multiple axes, but as more axes are drawn on the chart the less comprehensible and clear is the chart for the user. Also not supported as a standard feature is the ability to scroll the data on the time axis. The JFreeChart API must be extended to add that feature. Also possible, but not yet implemented, is a combination of the zooming functionality and the possibility to reload data.

Because of the aforementioned issues simple line charts are used to visualise time series and JFreeChart is used only as a backend API handling the creation of the charts.

### 4.1.3.1.2. Framework Design

It is necessary to easily reuse and integrate the new component for time series visualisation in different parts of the cids platform or any other software. As a consequence a framework that provides the necessary functionality to create time series visualisations and hides the implementation details of the chart API, as they are described in the following chapter, has been designed. The framework is designed in a generic way, imposing no restrictions on the concrete implementation of the time series visualisation. One benefit is that it is easy to extend the framework with new kinds of visualisations or backend APIs, or to replace existing ones. Another reason for this generic approach is that SUDPLAN has the requirement of two different kinds of visualisation, namely for simple and gridded times series. While simple time series can be easily visualised with standard line charts, gridded time series need more complex and customised visualisations. Before the design and functionality of the new framework is discussed, the TimeSeries API which is used to represent time series objects within the constructed time series visualisation framework is introduced.

### 4.1.3.1.3. The TimeSeries API

The Time Series API (TS-API) is being developed by the Austrian Institute of Technology and is described in 4.2.1. It is a part of the time series toolbox (TS-Toolbox) which is “a high level programming framework that allows efficient access to, processing, archiving and presentation of the semantically enriched time series.”\(^1\) It consists of generic interfaces to represent time series, which is the main reason it is used for data representation. It acts as a kind of adapter because it is easy for any user to develop their own implementation or an extension of an existing one. Furthermore, it abstracts the time series representation from the concrete visualisation API and the datasets used there.

The TS-API describes a time series as a set of slots and properties. The properties are valid for the whole time series and hold further information about it. Important properties that are used

---

within the framework are the *unit keys* that describe the unit the time series values are measured in and *value keys* that act as an ID to access the data values. A slot always contains a *Timestamp* which acts as an identifier. It can contain zero or more values which can be identified by a value key. The prevailing value keys are stored in a time series property. Figure 34 illustrates the structure of a TS-API time series.

![Figure 34: The fundamental structure of a time series in SUDPLAN](image)

The TS-API makes no assumption or limitations on the data that are stored, which allows the creation of gridded time series without special implementations or extension of the API, another benefit of using the Time Series API. But the TS-API has a further benefit. As already mentioned, the new component must be able to execute operations on time series data. The AIT TimeSeries Toolbox contains a module called *Formular 3* (F3) which allows definition and execution of operations on TS-API time series based on a customised input language. Operations on time series, their implementation in this framework and the functionality of F3 are introduced later.

### 4.1.3.1.4 Framework Conceptualisation

The basis of the framework is the interface *TimeSeriesVisualisation*. This Interface acts as the data model of the visualisation and basically offers methods to add and remove time series objects. *TimeSeriesVisualisation* defines a set of properties like the title of the visualisation. The use of properties enables each instance of a *TimeSeriesVisualisation* to be extended with individual properties. To keep the real visualisation of the time series data separate from the framework, the *TimeSeriesVisualisation* interface defines the method `getUI()`, which returns an instance of `JComponent`. As mentioned before this makes it possible to easily extend or replace the underlying visualisation. Each *TimeSeriesVisualisation* can define a *Toolbar* which offers the user specific interaction functionalities. To avoid integrating the toolbar at a static point within the visualisation user interface, the *TimeSeriesVisualisation* interface defines the `getToolbar()` method. This makes it possible to determine the position of the toolbar individually or to leave it out completely if not needed.

To simplify the usage and creation of concrete *TimeSeriesVisualisation*, the framework is extended with a factory class *TimeSeriesVisualisationFactory*. This class defines the factory method `createTimeSeriesVisualisation(type)`. The type
argument makes it possible to distinguish between visualisation for simple and gridded time series, which have totally different requirements. The usage of a factory allows it to generate multiple and different implementations of the framework and offers easy access to them. Therefore the factory method creates an instance of SimpleTSVisualisation, which is the default implementation for simple time series in case the visualisation type is simple, which corresponds in design and functionality to the implementation described later.

4.1.3.1.5. Event Lookup Mechanism

It can be necessary that another component needs to know when time series were added or removed from the visualisation. The selection of time series can also be interesting for other components. Finally, it is likely that a concrete implementation needs to define visualisation specific properties or behaviours. Therefore the framework defines different event notification mechanisms according to the observer pattern. In general, the prevailing events can be divided in two classes. The first class is necessary for every visualisation that is created by the framework and notifies listeners about removed or added time series, for example. The second class is visualisation specific, such as the selection of time series, and cannot be provided in a general way.

Because of this difference, the realisation had to be executed in two different ways. The event notifications that are valid for all visualisations were integrated directly in the interface TimeSeriesVisualisation. These are only those methods to add and remove listeners that are interested in changes of the stored time series set. Those listeners are described by the interface TimeSeriesListChangedListener. The interface contains only one method that is called whenever the stored set of time series has changed. The state of the properties can also be observed.
The event notification for all visualisation specific events as well as visualisation specific behaviour is defined in separate interfaces and must be implemented by the visualisation if it needs support for this event type or behaviour. Choosing this approach is much more flexible than defining all methods directly in the `TimeSeriesVisualisation` interface and allows fine grained control of the visualisation. Additionally it is much easier to define a new event notification mechanism and extend a visualisation to them if needed. But in doing so a new problem is created. The built in factory returns an instance of `TimeSeriesVisualisation`. How does the user of the factory know which event notifications mechanism and what visualisation specific behaviour is supported by the delivered `TimeSeriesVisualisation` instance.

To solve this problem the `TimeSeriesVisualisation` interface is extended with a lookup mechanism. A `TimeSeriesVisualisation` can be asked if it supports a specific interface. This is done by calling the method `getLookup()` which takes the class object of the interface as a parameter.

The lookup returns an instance of the interface if it is implemented by the `TimeSeriesVisualisation` class.
4.1.3.1.6. Comparison Operations

A requested feature for the time series visualisation framework is the ability to execute operations on time series. As mentioned before this task especially enhances the comparison of time series. The necessary extension of the former framework and the implementation of the operations will be topic of this section.

4.1.3.1.7. Framework Extension

An operation that can be executed on time series is represented by the interface `TimeSeriesOperation`. Because these operations must be executed from a `TimeSeriesVisualisation` and the result must be visualised there too, the `TimeSeriesVisualisation` interface is extended with methods to add and remove `TimeSeriesOperation` and a listener mechanism that makes it possible to be notified whenever an operation is added or removed from the visualisation. This flexible design makes it possible to add operations dynamically to the visualisation and to adjust the applied operations to the needs of the visualisation. It also is conceivable that the new operations are created and defined dynamically by the user. Of course this would cause further implementation effort, but the fundamental design is already flexible enough to tackle this challenge.

The operations are designed after the Command Pattern which is already realized in Java Swing in terms of `Java Actions`. Java Actions allow the definition of functionality at one place and access to it from multiple control elements. Furthermore they contain information like description texts and icons that are used to represent them in the user interface, the enabled state that allows it to enable or disable the execution of an action. The use of Actions is advantageous because they separate the execution code of the operation from the visual representation, and hence can be used for multiple visualisations at the same time. Simultaneously they are able to influence the visual representation of the operations in terms of defining the icons and text.

The loose coupling of operations and the visualisation as well as the use of Actions results in one problem. The method that is called if an Action is executed does not return any value. This means that the result of the operation must be communicated to the visualisation in a different way. Thus the `TimeSeriesOperation` interface is extended with a listener mechanism. After the execution of an operation all registered listeners are notified about the result.
The operation has no information about what time series it should use as input parameters. The possible parameters are determined by the selection of time series. The operation must offer the possibility to select the parameters as a subset of these selected time series. The two sets can be set with the corresponding methods `setParameters()` and `setAvailableTimeSeriesList()` that are defined in the `TimeSeriesOperation` interface. The parameters are represented as an `array` which leads us to the next problem. The position of the parameters has an operation dependent semantic which must be taken into consideration when determining them. This is done with a special user interface that visualises this operation dependent semantic and allows the user to order the parameters as desired.

To keep the creation process of new operations as simple as possible, an abstract class `AbstractTimeSeriesOperation` is created that takes care of all the necessary steps to keep the enabled state up to date, to determine the parameters, notify registered listeners about the result and execute the real calculation in a separate thread. Also a `DefaultParamOrderUI` which takes care of the aforementioned problems regarding determining the parameters is implemented and used by this class as default. `AbstractTimeSeriesOperation` defines the abstract method `calculate()` which contains the operation dependent calculation code. To implement a new operation it is only necessary to instantiate subclass `AbstractTimeSeriesOperation` and to implement the `calculate()` method.
4.1.3.1.8. Integration in the SMS

As a first step, the visualisation for simple time series is embedded in a concrete use case called ‘Information on the European Scale’. This use case defines how the user can extract environmental information from the visualisation of the downscaled European climate data. This visualisation of the European climate data is done with multiple layers in the cids cismap plugin that shows different information, such as maps. The cismap plugin is a full featured WMS/WFS client. WMS and WFS are standardized web services that allow the retrieval of cartographic data. In general cismap visualises a map layer that can be extended with a set of additional information layers. The map and the additional layers are retrieved from a WMS server.

In the above mentioned use case, one possible configuration of cismap shows a map of the European continent. The user extends this map with layers that visualise the desired European climate data. Such a layer represents one environmental factor, for instance temperature or precipitation, and basically consists of a pre-rendered image of a gridded time series. These information layers are visualised on top of the European map.

In the above mentioned use case, one possible configuration of cismap shows a map of the European continent. The user extends this map with layers that visualise the desired European climate data. Such a layer represents one environmental factor, for instance temperature or precipitation, and basically consists of a pre-rendered image of a gridded time series. These information layers are visualised on top of the European map.

If the user activates an information layer to allow feature information requests on it, the cismap plugin generates a FeatureInfoDisplay for this layer, and the WMS-Server is asked for the metadata necessary to request the corresponding Sensor Observation Service (SOS). The SOS is a standardized web service that allows the retrieval of sensor data. The SOS contains the time series for the European Climate data.

If the user now clicks on the map, a so called feature info request is actuated, and this is sent to the WMS–Server. In this case the server response contains the real world coordinates which are related to the position of the mouse click. In case the user has multiple information layers in the map, a feature information request for each activated layer is actuated. The coordinates and the previously retrieved SOS metadata are used to request a simple time series from the SOS which is related to the cursor position. This simple time series can be visualised with the new framework implementation for simple time series.
4.1.3.1.9. Retrieval of Multiple Time Series

The problem with visualising multiple time series is that each click on the map actuates a new feature information request for each activated layer, the server response only contains a single time series, and the corresponding display only visualises the new retrieved data. The FeatureInfoDisplay that visualises the information is extended with a hold flag. If the hold flag is set, the display takes care that all the information from all earlier requests is kept in the visualisation. To let the user control this behaviour a checkbox is added to the user interface of the corresponding FeatureInfoDisplay.

4.1.3.1.10. Multiple Axes

Another limitation of the cismap framework was that it generated a separate FeatureInfoDisplay for each layer. Because the individual environmental variables are separated in different layers to represent them individually on the map, it was not possible to combine the requested information of different layers in a single FeatureInfoDisplay.

JFreeChart supports charts with multiple axes by default and comes with all the necessary functionality to manage and display them. A JFreeChart object consists of a so called plot area. This is the area where the dataset of the chart, for instance multiple time series, and the corresponding axes are drawn. Axes can be arranged at all four sides of the data area. The whole plot also has an orientation to instantly switch the position of x and y axis. A plot is represented by an instance of Plot. JFreeChart also defines a set of subtypes that predefines the type of the used axis. As time series charts represent X/Y –values, a XYPPlot is used which demands that instances of ValueAxis are used to represent the x and the y axis. The Plot offers methods to
add multiple x and y axes. They are used to generate separate y axes for each individual environmental factor like temperature or precipitation which usually have different units and therefore need individual scales.

![Diagram of JFreeChart Class Structure – Multiple Axes](image)

**Figure 41: JFreeChart Class Structure – Multiple Axes**

Basically all time series that are added to the chart are mapped to the primary axes of the chart. The primary axes are the ones which are generated during the instantiation of a JFreeChart object. This mapping ensures that the range of the axis always is in a consistent state with the datasets that are mapped to it. It is necessary to adapt this mapping to the new situation. To do this, the method `mapDatasetToRangeAxis(int datasetIndex, int axisIndex)` is used.

### 4.1.3.11. Time Series Selection

One issue that makes it necessary to extend the underlying JFreeChart API is the selection of time series in the chart. JFreeChart does not offer the ability to select single or multiple datasets within a chart. But this functionality is needed for multiple reasons. Selection of time series is essential to offer the user time series dependent interaction and information. The user should therefore have the ability to select time series to execute operations on them, to reflect the spatial geometry of the time series in cismap in order to show the user the spatial context of the data, and to remove single time series from the visualisation.

In JFreeChart, each dataset is drawn by an individual renderer. For time series charts a renderer is defined by the `XYItemRenderer` interface, and JFreeChart offers a set of previously implemented renderers, such as `XYLineAndShapeRenderer`, which is used as the default for time series charts and as the default for this implementation. An `XYLineAndShapeRenderer` draws, as the name suggests, the dataset as a combination of an individual shape for the data points within the dataset and a line between these data points. As a renderer is used to render a single dataset the selection status is stored directly in the renderer.
For this, a renderer class is derived from `XYLineAndShapeRenderer`. It contains the selection status and paints the corresponding dataset. The selection is visualised with a drop shadow, as it is known, from trees or lists. This helps the user to build his mental model of the functioning of the new component. The rendering of a time series dataset in JFreeChart is done in two steps. The first step draws the line between data points, the second one draws the shapes for the data points themselves. To draw a drop shadow for the selection the method `drawFirstPassShape()`, which takes care of drawing the line between the shapes, is overridden. If the selection flag is set, a second lightly transparent line is drawn on top of the real line. After that, the selection status of a time series still must be triggered by users’ input. Although selection is not supported as a standard feature by JFreeChart it offers a customised event notification for mouse clicks. This event notification can be used by registering a `ChartMouseListener` to the chart object. This listener is notified whenever the mouse moves over the chart or a click is performed on it. The corresponding event of that notification contains an instance of `ChartEntity` which represent the entity that is at the coordinates of the mouse click. Unfortunately JFreeChart does not distinguish these entities in a very detailed way. Hence it is not possible to identify the clicked entity as a time series dataset if the user clicks on the line between two data points and not at the data point itself.
4.1.3.1.12. Time SeriesScrolling

As mentioned in the introduction, one essential interaction method is to view the data in detail as well as in an overview and to navigate through the data. This is also one of the requirements of the new component. Charts created with JFreeChart can be zoomed in and out to view regions of interest in varying detail. During such a zoom action, the visual appearance of the chart is updated, which means that the axis labels are updated to the new viewing region and the datasets are redrawn. But in doing so, the user has no possibility to scroll the data over time. If they want to see the data in the same detail but for a different region they need to zoom out and then zoom in again. To avoid this, the chart is extended with a scrollbar that offers the user the ability to scroll over the whole time period of the dataset when zoomed in. To do this, the scrollbar must handle the time period that is represented by the chart’s x-axis. The x-axis in a time series chart is always an instance or subtype of DateAxis. A DateAxis represents the values as a date. This is a serious problem, because dates in Java are represented as long values because a date is the time in milliseconds since midnight 1.1.1970. However, the scrollbar can only handle integer values. Therefore it is necessary to map the axis long values to integer values. In doing this the time period of the axis is divided by the number of possible integer values. This allows it to resize the scrollbar extent whenever the x-axis range has changed by a zooming event and to adopt the range of the DateAxis if the scrollbar is moved. In the case of the mapping between the long date values and integer scrollbar values, zooming in the data is only possible up to a limited granularity. This granularity depends on the time period that must be visualised in the overview. A possible solution of this disadvantage is to provide only two buttons that scroll the data to the left and to the right.

4.1.3.1.13. Spatial Context of Time Series

It is useful to show the spatial context of a time series directly during the retrieval and not only with the selection of it. Until now, the cismap plugin just displayed a standard icon, called feature info icon, for the last click on the map. Furthermore the feature info icon had no relation to the results of the feature info request that was actuated. Even if this use case is the first where it will be necessary to show multiple and customized symbols during a feature info request in cismap, such a requirement will possibly appear in the future again. Therefore the solution to that issue needs to be generic and easily applied to other situations.
A possible solution to this problem is to introduce a new interface in cismap, namely `MultipleFeatureInfoRequestDisplay`. This interface consists of two methods. The first one returns the status of a hold flag used to determine that the FeatureInfoDisplay visualises also old information requests. The second one returns a collection of `SignaturedFeatures`. In cismap a `Feature` is an object that can be displayed on the map and a `SignaturedFeature` additionally defines an icon that should visualise a relation to the information of the feature info request.

In this case this icon consists of the shape used to represent data items in the time series chart.

![Figure 44: Time Series Retrieval v2](image)

When the user activates a layer for feature info requests, cismap creates a `FeatureInfoDisplay` for that layer. As a consequence of the new interface, cismap is adapted to see if this `FeatureInfoDisplay` implements the new interface. If so, cismap registers itself as a listener to the display to be notified if the collection of `SignaturedFeature` has changed. If the user now clicks on the map and actuates a `feature info request`, the display creates a `SignaturedFeature` for this request and notifies cismap about that. Cismap then displays a feature info icon for each `SignaturedFeature` that the notification of the display contains. The standard feature info icon is overlaid with the icon of the `SignaturedFeature`. Because the feature information icon is customizable, and therefore the size and position where the overlay icon can be drawn can be changed, the feature information icon is extended with meta information that describes the position and the size of the overlay area and the background colour used.
Because multiple layers can be activated for feature information requests, it can occur that both *MultipleFeatureInfoRequestDisplay* and normal displays are activated at the same time. Therefore it is necessary to emphasise the icon for the last feature info request to show the spatial context for normal displays too. This is done by using a different colour for the feature info icon.

Figure 45: Time Series Spatial Context
4.1.3.2 Asynchronous Model Execution Framework

SUDPLAN Applications integrate a large variety of models –Common Services and Local Models - that can be executed via the SMS. The execution time of these models differs from seconds to several weeks. Thus the SMS provides an Asynchronous Model Execution Framework so that implementers can integrate models quickly and easily without the burden of status polling and user notification. Additionally the framework offers automatic unfinished execution recovery so that model status monitoring can be continued if the SMS is reopened. This is especially useful for long running tasks.

4.1.3.2.1. Framework Classes

Figure 46 depicts a UML class diagram that contains the core classes of the Asynchronous Model Execution Framework.

![Figure 46: Asynchronous Model Execution Framework](image)

The most relevant classes and their responsibilities are listed in the following.
This description focuses the asynchronous model execution framework and may not necessarily be sufficient to gain a comprehensive understanding of the SUDPLAN Model Management Framework, let alone the cids Application Framework.

- **Manager:** The `Manager` interface is the most basic interface of the SUDPLAN Model Execution Framework. Any model integration must provide three classes: One responsible for the model input, model output and model execution, respectively. Each of the classes has to adopt the `Manager` interface.

- **Executable:** Each class that is responsible for the actual model execution must adopt the `Executable` interface, additionally.

- **ModelManager:** The `ModelManager` interface simply merges the `Manager` and the `Executable` interfaces for reasons of convenience.

- **AbstractModelManager:** The `AbstractModelManager` class adopts the `ModelManager` interface and provides implementations for the required operations. Moreover it offers facilities to handle model execution progress. However, it forces an actual model manager implementation to be able to actually perform the model execution and to be able to create a so-called `CidsBean` (`CidsBeans` are part of the cids Application Framework and are not further described here) that represents the output of the model. Model integrators are encouraged to subclass this class as it handles most of the task involved in the model execution by default. However, it does not provide support for asynchronous execution by default.

- **AbstractAsyncModelManager:** This is one of the core classes involved in the Asynchronous Model Execution Framework. Model integrators must subclass this class to take advantage of it. The `AbstractAsyncModelManager` class forces the adopter to provide some more information that is necessary to integrate smoothly with the AMEF, but takes care of model execution progress and potentially download dispatch on execution finish.

- **AbstractModelRunWatchable:** This is another core class of the AMEF. It adopts the `Watchable` as well as the `Download` interface and subclasses the `Observer` class. This `Watchable` implementation provides default settings to instruct the `DownloadManager` to potentially download the model results and provides the preferred status callback implementation. The only two things the adopter of this class must take care of is an appropriate way to provide status information of the specific model execution and an appropriate way to download the model results if this is necessary.

- **Watchable:** The `Watchable` interface describes the necessary operations to monitor a specific resource. `Watchable` instances can be submitted to the `ProgressWatch` class.

- **ProgressWatch:** The `ProgressWatch` class is a singleton instance that is responsible for handling of `Watchable` instances. Thus it polls the model execution status using the `Watchable` interface and propagates the status via the provided status callback.

- **Download:** The `Download` interface describes the necessary operations if a resource shall be downloadable via the `DownloadManager` (the `DownloadManager` is part of the cids Application Framework and is not further described here).

- **SudplanStartupHook:** The `SudplanStartupHook` is an implementation of the `StartupHook` interface and thus is responsible for the recovery of unfinished runs on SMS startup, so that they can be monitored again.
• **StartupHook**: This interface is part of the cids Application Framework and provides a means for interested parties to perform operations on application startup.

The Asynchronous Model Execution Framework is highly parallelized and thread-safe. Thus adopters won’t have to take care of threading and can directly implement the required operations of the framework classes in a synchronous (not synchronized) fashion.

### 4.1.3.2.2. Framework Sequence of Actions

This section provides an overview of the sequence of actions for a single model execution via the Asynchronous Model Execution Framework and thus illustrates how it works. However, in order to keep things simple threading is mostly omitted. Moreover some workflows that are not directly related to the model execution or that are part of other frameworks are indicated by a “virtual” operation call. Ultimately the depicted sequences may not be exhaustive, in order to keep things simple.

#### 4.1.3.2.2.1. Initiation of the Model Execution

![Figure 47: Initiation of the Model Execution](image)

- The model execution is initialised through a call of the `execute()` operation. In most cases this by the SMS-internal `ExecutableThreadPool`.
- The `AbstractAsyncModelManager (AAMM)` instance indicates the start of the model by calling the `fireStarted()` operation.
- After that the `internalExecution()` operation calls `prepareExecution()`.
- The `prepareExecution()` operation implementation is actually responsible the start the specific model and has to make sure that a call to `createWatchable()` will provide an adequate `AbstractModelRunWatchable (AMRW)` implementation for the specific model execution.
• The AAMM fetches the AMRW via createWatchable() and submits it to the ProgressWatch.

4.1.3.2.2. Execution Status Monitoring

![Figure 48: Execution Status Monitoring](image)

• The ProgressWatch is responsible for monitoring the status of all submitted Watchable instances. Thus it originates polling the requestStatus() operation of the Watchable.
• The Watchable instance creates a new ProgressEvent reflecting the current status of the specific model execution and returns it.
• The ProgressWatch in turn creates a new ProgressEvent on basis of the ProgressEvent returned by the Watchable instance but sets the actual AMRW as event source.
• After that the ProgressWatch requests a ProgressListener using getStatusCallback(). By default the AMRW loads its corresponding AAMM instance and returns it
• The previously created ProgressEvent is then dispatched to the AAMM.
• If the status of the model execution is finished the ProgressWatch deregisters the corresponding Watchable.
4.1.3.2.2.3. Model Execution Status Event Processing

- The status of a model execution is received by the specific AAMM instance through a call to the progress() operation.
- In case of a PROGRESSING state the fireProgressed() operation is used to propagate the model execution state.
- In case of a BROKEN state the fireBroken() operation is used to indicate that the model execution has stopped and will not be recovered.
- In case of a FINISHED state:
  - If the needsDownload() operation indicates that a download is not necessary the AAMM uses the fireFinished() operation to propagate that the model execution is successfully stopped. The fireFinished() operation automatically uses createOutputBean() to fetch the model results and notifies the user about current state.
  - If the needsDownload() operation indicates that the results must be fetched before the execution is of value for the initiator the AAMM initiates the download via the downloadResults() operation
    - The createDownloadObserver() operation is used to provided a means to watch over the download progress. The download observer is...
initialised with the Watchable instance associated to the current model run and is additionally added to it as an actual Observer instance.

- Finally the Watchable instance is submitted to the DownloadManager via add().

### 4.1.3.2.2.4. Model Result Download Processing

![Diagram](image)

Figure 50: Model Result Download Processing

- If the update() operation of the download observer receives the state COMPLETE it detaches itself from its AMRW instance.
- After that it calls the getCidsBean() operation of the AMRW and tries to load the AAMM instance that is responsible for the particular model run and thus its download.
- Finally a successful model execution is indicated by the fireFinished() operation.
- fireFinished() uses createOutputBean() to fetch the model results and ultimately the user is notified of the status of the particular model execution.
4.1.3.2.2.5. Model Monitoring Recovery on Startup

- On application startup `applicationStarted()` operation of the `SudplanStartupHook` is invoked.
- The `SudplanStartupHook` has facilities to discover unfinished model runs and receives a list of them.
- For each of the unfinished runs:
  - The `SudplanStartupHook` loads its corresponding `AAMM`
  - It uses the `AAMM`'s `createWatchable()` operation to get a `AMRW` instance for the specific run
  - The fetched `AMRW` is then submitted to the `ProgressWatch`.

The Framework is part of the current release of the SMS and thus is available for all Pilot Applications.
4.1.4 Third Year Development

Based on the second year developments the focus of year three’s work will be on:

- Integration of the Hydrology Common Service
- Enhancement of the Air Quality Common Service Integration
- Comparison Features for gridded time series
- General GUI Enhancements towards a stable product

4.1.5 Current Release Feature Summary

The current release of the SMS Framework supports a number of vital features that are used to access, visualise and compare Common Service as well as local models results. In summary, the features included in the second year release of the software are:

- Model management (information related to a model, i.e. meta information)
- Enhanced Asynchronous model execution (incl. model state persistence)
- Management of model runs, results and parameterization
- Basic model result visualization (1D time series, 2D maps)
- Model Result (Scenario) Comparison (1D time series) including visual comparison support, time series operations and 2D map interaction.
- Integration of temporal aspects of 2D map visualisations
- Search and discovery of objects of concern (e.g. results, scenarios)
- OGC SOS (TS-API based), SPS (TS-API based), WMS and WFS integration capabilities.
- Support for Rainfall (time series & IDF)
- Air Quality Common Services
- Pan-European Common Services (climate change parameters)
- Local model integration support
- Integration facilities for local data (time series)

The current version of SMS related software (cids SUDPLAN extensions) can be found at http://sudplanwp3.cismet.de/sms/.
4.2. Model as a Service Integration

The main objective of this part of the SMS is to provide the means to control model implementations and access model results, including both SUDPLAN Common Services and local pilot specific models, via standardised web services. The selected standards are members of the OGC SWE [SWE, 2007] family, specifically SOS (Sensor Observation Service) and SPS (Sensor Planning Service), which are used for model result access and model control. This part of the SMS can be used to access the corresponding common service (see D4.1.1 – Concerted Approach Report V1) as well as to encapsulate local models as in some of the four pilot applications of SUDPLAN.

Within SUDPLAN we concentrated on the use of the OGC service interfaces. The main reasons were:

- The OGC service interfaces are an accepted standard in the GIS community, and cover a large number of use-cases relevant to environmental applications.
- All OGC specifications are freely available to everyone.
- All OGC service specifications share common data encodings and descriptions such as O&M – Observation and Measurement [OM1, 2007], GML - Geography Markup Language [GML, 2004], and SensorML - Sensor Model Language [SensorML, 2007].
- Implementations of libraries and some ready to use services are already available with open source.
- The DoW requires the use of an open approach in consideration of the technical requirements of SISE [SISE, 2009] (See D3.1.2, REQ-DoW-2 ff).

Additionally, the use of these established standards enables the integration of SUDPLAN services and the SMS with existing as well as emerging data and model services.

A precondition for the integration of data services is that all data need to be self-describing [ORCHESTRA, 2008] which means that there is information about the values, such as unit of measurement, description of phenomena, precision and uncertainty, and methods of measurement in the form of sensor descriptions. The same is true for models as we expect to access more models over time and they should be usable without prior knowledge of any details about them. There are many standards for data transport and remote service invocation. SANY SensorSA [SANY, 2009] and Fusion Architecture [Sany FMA, 2010] documents already anticipate most of this and were therefore used as important sources of requirements regarding the Model as a Service Integration Building Block of the SMS.

4.2.1 Components and APIs Used

The implementation of SOS and SPS related software is based on the Time Series Toolbox (TS-Toolbox) API from AIT. The TS-Toolbox API provides the means to conveniently deal with arbitrary time series.
We decided to use the TS-Toolbox because it represents a good starting point from which to implement dedicated services able to wrap the various existing models needed in SUDPLAN and to establish the basis for the integration of new local models through standardised service interfaces. In the SANY project, we found that the use of existing SOS and SPS implementations, e.g. from 52° North Initiative [SOS52N, 2011] is not feasible as they are complete systems, and they are not built to act just as an interface implementation to wrap existing models or data bases. Many other parts of the TS-ToolBox, especially on the client side, can also be used or adapted to suit SUDPLAN needs.

In the following a short introduction on the TS-Toolbox architecture and the related APIs is given. More information on the TS-Toolbox can be found at http://ts-toolbox.ait.ac.at.

TS-Toolbox is a high level programming framework that allows efficient access to and processing, archiving and presentation of semantically enriched time series. It consists of three layers (Figure 52: Elements of the TimeSeries ToolBox): the "applications" layer provides examples of complete TS-Toolbox applications with CLI, GUI and web-service interfaces; the "components" layer provides the functional building blocks for commonly used functions; and the "TS-API" layer provides the basic interfaces and methods for presentation and manipulation of semantically enriched time series.

The functionalities implemented by the TS Toolbox components provide application developers with higher level building blocks than typical general purpose libraries, and allow rapid development of full-fledged service, GUI, and CLI applications. Moreover, the TS-Toolbox based applications are highly modular, network-aware, and easily re-configurable, and the use of TS-API interfaces simplifies the task of extending and adapting the TS-Toolbox applications to new environments. The main advantages of the TS-API are:

- Data from different legacy systems, including local models and related environmental, geographical or background data, can be easily integrated, processed, visualized, and made available to a larger audience by means of standardized service interfaces.
• Its pipe-oriented architectural design greatly simplifies the task of component and data flow configuration within an application, e.g. using the output of a certain model (SUDPLAN Common Service) as the input to another model (pilot-specific local model).

• The components can be easily chained, e.g. in order to provide more sophisticated processing capabilities, and used in parallel (e.g. asynchronous model execution), in order to provide alternative means for accessing, storing and presenting the data.

• Components can be easily extended or replaced with alternatives, e.g. in order to access new types of data, integrate new models, or improve the processing or storage performance.

The TS-Toolbox "components" provide the functional building blocks for commonly used functions, such as:

• Sensor configuration and access to sensor data. For example, the AnySenDataHandler provides a means to access various sensors accessible over serial and network interfaces.

• Read- and/or write- access to time series stored in services, files and databases. For example, the SOSDataHandler provides access to standardised Sensor Observation Service, the CSVSimpleDataHandler to ASCII files and the GenericDBDataHandler to relational databases.

• Service interfaces. For example, the Remote DataHandler allows exchange of time series between two TSToolbox applications over the network.

• Processing and annotation of the time series. In particular, the F3 Processor component provides a generic functional language for manipulation of the time series.

• Control components provide a convenient way to dynamically control the data flow and the behaviour of the DataHandler and Processing components.

The TS Toolbox is designed with extensibility in mind, and more components, such as model integration and management components developed in SUDPLAN, will be added in the future.

4.2.2 First Year Development

In the interest of model and service integration into the SUDPLAN SMS three tasks has been performed:

• Definition of a data and meta-information encoding conformant to OGC standards
• Integration of a client part into the SMS
• Development of a generic service providing OGC SOS and SPS interfaces to encapsulate models
The generalised course of action of a model invocation is shown in Figure 53: Invocation of a Model Encapsulated as a Service.

![Figure 53: Invocation of a Model Encapsulated as a Service](image)

### 4.2.2.1 O&M Encoding of Time Series of Fields

Based on the size of the data, a distinction is made between parameters for a model run and input data. While the parameters are typically of simple type and small in size (except for calibration data, for example), the input data for a model are complex in nature and quite commonly of several GB in size. Because the model needs fast access to the input data these data have to be uploaded to the model site. The user of the model does this (sometimes over institutional boundaries) through an implementation of the SOS interface. This interface is also used to enumerate and retrieve the model results. Model input and result data transferred through the SOS interface are encoded using the O&M (OGC Observation and Measurement) [OM1, 2007] information model.

The O&M encoding is straightforward for time series of scalar values and used by many SOS implementations such as 52° North [SOS52N, 2011]. The encoding of time series of coverages is not that well defined. Observations and Measurements - Sampling Features (O&M-SF) [OM2, 2007] specification provides a means to encode discrete coverages and provides dedicated elements to do so, but it lacks dedicated elements necessary to describe continuous coverages.

The SANY ‘Fusion and Modelling Architectural Design’ [SanyFMA, 2010] document describes two methods for encoding coverages in O&M. Both use the O&M-SF sa:SamplingSurface element. While there is no dedicated element in O&M-SF v1.0 to specify a grid on which the sampling takes place, both methods describe the sampling points and grid by embedding its description in sub-elements of the sa:SamplingSurface, which was not designed for this purpose.

In SUDPLAN an additional method has been considered for describing continuous coverages. The optional SOS method DescribeFeatureOfInterest allows for retrieval of the feature type description (xml schema) for a given feature of interest. This allows us to introduce a new namespace containing additional Sampling Feature types.

The new SamplingGrid type inherits from the sa:SpatiallyExtensiveSamplingFeatureType defined in O&M-SF and contains a gml:RectifiedGrid element that describes the rectified grid on
which the sampling takes place. The advantage of the mentioned inheritance is that the sampledFeature relation is retained. SUDPLAN SamplingGrid schema and one Sampling-Grid instance example are shown below.

**SamplingGrid schema:**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<schema xmlns="http://www.w3.org/2001/XMLSchema"
    xmlns:xlink="http://www.w3.org/1999/xlink"
    xmlns:gml="http://www.opengis.net/gml"
    xmlns:sa="http://www.opengis.net/sampling/1.0"
    xmlns:aitsa="http://www.ait.ac.at/sampling"
    targetNamespace="http://www.ait.ac.at/sampling"
    elementFormDefault="qualified"
    attributeFormDefault="unqualified">

<import namespace="http://www.opengis.net/gml"
        schemaLocation="/gml4sos.xsd"/>

<import namespace="http://www.opengis.net/sampling/1.0"
        schemaLocation="http://schemas.opengis.net/sampling/1.0.0/samplingManifold.xsd"/>

<element name="SamplingGrid" type="aitsa:SamplingGridType" substitutionGroup="gml:_Feature"/>
<complexType name="SamplingGridType">
    <complexContent>
        <extension base="sa:SpatiallyExtensiveSamplingFeatureType">
            <sequence>
                <element ref="gml:RectifiedGrid"/>
            </sequence>
        </extension>
    </complexContent>
</complexType>
</schema>
```

**SamplingGrid instance example:**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<SamplingGrid xmlns="http://www.ait.ac.at/sampling"
              xmlns:gml="http://www.opengis.net/gml"
              xmlns:xlink="http://www.w3.org/1999/xlink"
              xmlns:sa="http://www.opengis.net/sampling/1.0"
              xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
              xsi:schemaLocation="http://www.opengis.net/gml http://schemas.opengis.net/gml/3.1.1/base/gml.xsd
                              http://www.ait.ac.at/sampling ./SamplingGridSchema.xsd ">

    <gml:description>Sweden grid</gml:description>
    <gml:name>Sweden Grid</gml:name>
    <gml:location/>
    <sa:sampledFeature xlink:href="urn:MyOrg:feature:sthlm_1"/>
    <gml:RectifiedGrid dimension="2">
        <gml:limits>
            <gml:low>0</gml:low>
            <gml:high>50 60</gml:high>
        </gml:limits>
        <gml:axisName>x</gml:axisName>
        <gml:axisName>y</gml:axisName>
        <gml:origin>
            <gml:Point srsName="urn:x-ogc:def:crs:EPSG:3021">
                <gml:pos>6546000.0 1580000.0</gml:pos>
            </gml:Point>
        </gml:origin>
        <gml:offsetVector srsName="urn:x-ogc:def:crs:EPSG:3021">0 2e-005</gml:offsetVector>
    </gml:RectifiedGrid>
</SamplingGrid>
```
4.2.2.2 Using UncertML to Describe Statistical Data

The descriptive model language Uncertainty Markup Language – UncertML [UncertML, 2007] developed by the INTAMAP project can be used to encode the accuracy of the observation collection. The SUDPLAN rainfall downscaling service generates a 2D table of the predicted precipitation values for the total seasonal accumulation (TOT), maximum 30-min intensity (MAX), and frequency of occurrence (FRQ).

Because of the statistical characteristics of these data, UncertML could be used to encode them, similar to the way uncertainties in sensor data and model outputs were encoded in the SANY project. This would mean treating these data as descriptions of the time series of rainfall, not as an independent result. At the same time these data have the characteristics of a time series, meaning that they provide the above mentioned statistical information for every season. At this point no decision has been taken about whether these data should be encoded in SUDPLAN as observations (using O&M), or as observation uncertainties (using UncertML).

4.2.2.3 Using SensorML to Describe Models and Required Parameters

The SOS and SPS interfaces provide process descriptions encoded in SensorML through the describeSensor operation. In SUDPLAN, the process is a model and can be described as a non-physical (pure) process. The information provided in the form of a SensorML document can be quite extensive, encompassing model inputs, parameters, outputs, the model algorithm itself, and details of the implementation module. Currently, our applications require descriptions of constant model parameters necessary for the human interpretation of the model results. This includes model identification, responsible party, input and output model. Our processing services act as clients to several Sensor Observation Services. The following simplified SensorML document shows basic model identification as well as the inputs and outputs of the rain downscaling model used in SUDPLAN. The model takes as input a SOS offering name containing the historical rain measurements as well as a future timestamp around which the downscaling results are generated. The model generates a timeseries of coverages with the resulting data described in the element “Downscaled rain”.

```
Based on these encodings a client part (called a DataHandler in the TimeSeries ToolBox context) was implemented and integrated into the SUDPLAN SMS.

After implementing a generic server providing SOS as well as SPS functionality the integration of the Common Service started with

- Climate scenario data
- Rainfall downscaling for rain time series
- Air Quality downscaling

In general all Common Services models require the upload of input data (handled by an SOS interface), the invocation of the actual model run (handled by an SPS interface) and the download of results (again handled by an SOS interface). This is shown in more detail in Figure 54: Model Invocation Details.
4.2.3 Second Year Development

For the model and service integration into the SUDPLAN SMS the following tasks have been performed:

- Further development in the generic OGC SOS and SPS service and client counter part.
- Providing a service offering climate scenario data
- Providing a service for rainfall time series downscaling
- Providing services for the Linz pilot: Sensor data and local model
- Providing a service for rainfall IDF curves downscaling

Contrary to the first year’s prioritisation the integration of hydrology has been moved to the 3rd year. Instead the IDF downscaling was implemented in the 2nd year. The reasons for this are concrete and reflect higher priority user needs of the pilot applications.

4.2.3.1 Rainfall Downscaling Services

There is an important difference between the two rainfall downscaling services. The long rain time series (more than 10 years, at least one value every 10 minutes) allows access to long-term efficiency requirements, as it is done in the Linz pilot. But it is not easy to use this long time series to support access to extreme events. On the other hand IDF curves don’t tell anything about the overall amount of rain in the future. Instead they reflect the probability of a specific rain intensity and duration. This is needed in the Wuppertal pilot to assess flooding risks.

Technically the rainfall time series downscaling takes a rain time series as input and projects this time series to a future period under the assumption of a specific climate scenario. What was not explicitly stated in this sentence is the meta-information contained in the time series, in particular the time interval of the input rain time series and matching coordinates. In contrast to time series downscaling IDF downscaling takes an IDF curve as input and projects this to a future period under the assumption of a specific climate scenario. But in this case the time interval for which the input IDF curve is valid, as well as the coordinates, need to be given explicitly.

4.2.3.2 Linz Pilot Application Services

After integration of the local model a complete model run cycle involving access to local data, the upload of these data as input to a common service, running the common service, downloading the result from the common service, and uploading this result as input to a local model can be demonstrated. These steps are followed by a local model run and the download of the results from the local model back to the SMS.

An example of how this is used in the Linz pilot is shown in Figure 55: Complete Model Run (Linz).
4.2.4 Third Year Development

The plans for the 3rd year include:

- Finalisation of the air quality downscaling (upload of expected future local emissions)
- Integration of the hydrology models
- Integration of more sensor data in the context of the Linz pilot.

4.2.5 Current Release Feature Summary

The focus of the second implementation cycle was to complete the development to support the access to most of the downscaling functionality through a set of common services. In particular, dedicated SOS and SPS services have been developed that are accessed from the SMS framework to execute a model (SPS) or retrieve model results and upload input data and parameters (SOS). To facilitate easy integration into the platform the software comes with a set of client components (stubs/proxies) to easily access model related information without the need to deal with the service itself.

The current release supports a number of vital features that are used to access Common Services implementing OGC service interfaces and which can be used to control local models.

- Access to local data through SOS
- Upload model input data through SOS
- Model execution through SPS
- Access to model results through SOS

The results are accessible at [http://ts-toolbox.aic.at/SUDPLAN/staging/](http://ts-toolbox.aic.at/SUDPLAN/staging/).
4.3. Advanced Visualisation Component

According to the DoW SUDPLAN SMS functionality will include “an advanced 3D/4D visualisation component for the visualisation and animation of 3D results and predictions, in particular using the 3D landscape.” This component will help the planners, modellers and decision makers to gain deeper insights into the correlations of phenomena related to their particular workflow. Unlike the previously described parts of the SUDPLAN SMS, the Advanced Visualisation Component has to be built from scratch. This implies several basic tasks which must be performed, besides the actual implementation efforts, such as component design and state of the art research. The efforts carried out in the first and second development phase will be described briefly in the following paragraphs.

In order to meet all of the requirements regarding the visualisation of the SUDPLAN SMS stated by the various formal documents (DoW, D3.1.2 - Requirement Specification V1 etc.) substantial research and evaluation had to be done. This was necessary in order to guarantee a suitable and flexible visualisation solution. The SUDPLAN SMS, more precisely the Scenario Management System Framework described in paragraph 4.1 - Scenario Management System Framework, is based on Oracle’s Java technology (in the following only referred as Oracle). Since the Advanced Visualisation Component will become an integral part of the final SUDPLAN SMS, it also has to be based on the same platform-neutral and web-based technologies. Platform neutrality and the ability to invoke the SMS over the web impose certain restrictions on the selection of 3D visualisation APIs. To avoid a proprietary solution that is limited in its interaction capabilities with the SMS Framework, Oracle’s own high level API Java 3D [Oracle, 2011] and low level OpenGL Java bindings, such as JOGL, were chosen for the implementation of the Advanced Visualisation Component. Due to reasons explained in section Fel! Hittar inte referenskälla. and Fel! Hittar inte referenskälla. the underlying framework was changed to the World Wind Java SDK in the course of the second year.

The goal of the first development cycle was first to create a running system which visualises pilot data related to the Stockholm (Södermalm) pilot. The idea behind this is to incrementally enhance the functionality. In the first version the data were opened and processed directly, but this approach will be gradually replaced by a service-oriented concept. In the course of the project the visualisation component will evolve over each development cycle. To achieve the goals planned for the second development cycle and to accommodate for new and more detailed requirements (general and pilot specific) the underlying framework needed to be changed. Using the World Wind Java SDK it was possible to incorporate the pilot specific data more easily and progress towards the envisaged service-oriented concept.

The overall goal is to produce a flexible and modular component which can be used in any application which has a need for geospatial visualisation in 3D. Special emphasis is placed on the reuse of available APIs and software. Through the course of the project we will use suitable and stable open source software as much as possible. Additionally, we will use publicly available proven geospatial standards such as WMS, WFS etc. in order to facilitate the easy integration of new and existing content for visualisation.

4.3.1 Components and APIs used

In contrast to the initial development (Year 1) it became evident in the second year that it will not be possible to accommodate all (previous and new) user requirements with a Java3D based,
built from scratch, Advanced Visualisation Component within the timeframe of the project. Therefore, a switch in the components used and APIs was necessary. It was decided, in agreement with the work packages involved and the consortium, to use the freely available World Wind Java SDK component as basis for the further development of the Advanced Visualisation Component. After the integration of the World Wind SDK it was thus possible to focus only on the visualisation and animation of 3D results and predictions, in particular using the 3D landscape. More detail on the decision process is given in chapter 4.3.3 Second Year Development.

The following paragraph gives a short overview of the functionalities already provided by the World Wind SDK.

The World Wind SDK is a free and open source Java-API for a virtual globe released under the NASA Open Source Agreement (NOSA). The framework provides a powerful platform for giving the SMS the means to express, manipulate and analyse data of interest. World Wind provides many features for displaying as well as interacting with geographic data and representing a wide range of geometric objects. Moreover, extending the API is simple and easy to do. Following an extract of important World Wind features:

- Open-source, high-performance 3D Virtual globe API and SDK
- Open-standard interfaces to GIS services and databases
- Capable to display high-resolution imagery, terrain, and geographic information from any open-standard public or private source
- Huge collection of high-resolution imagery and terrain from NASA servers
- Supports Coordinate System: Lat/Lon, UTM, MGRS
- Supports of GeoTIFF, JPG, PNG, and JPEG2000
- Supports standard GIS formats: Shape file, KML, GML, GeoJSON
- Different Navigation Modes are being supported
- Supports visualization for stereoscopic displays

Finally, organizations across the world use and support the on-going development of World Wind to monitor weather patterns, visualize cities and terrain. With World Wind taking care of the basic concepts of visualizing geographic data on a virtual globe, we are now able to focus on solving the domain specific problems and to focus mostly on the visualisation and animation of 3D results and predictions, in particular using the 3D landscape.
4.3.2 First Year Development

**Note:** Due to the change from Java3D to the World Wind Java SDK most parts of this section are obsolete but are left in the document for completeness.

In this paragraph a short introduction to the Java 3D API is given and references are provided for further study. The Java 3D tutorial describes Java 3D as follows:

“The Java 3D API is an interface for writing programs to display and interact with three-dimensional graphics. Java 3D is a standard extension to the Java 2 JDK. The API provides a collection of high-level constructs for creating and manipulating 3D geometry and structures for rendering that geometry. Java 3D provides the functions for creation of imagery, visualizations, animations, and interactive 3D graphics application programs. The Java 3D API is a hierarchy of Java classes which serve as the interface to a sophisticated three dimensional graphics rendering and sound rendering system. The programmer works with high-level constructs for creating and manipulating 3D geometric objects. These geometric objects reside in a virtual universe, which is then rendered. The API is designed with the flexibility to create precise virtual universes of a wide variety of sizes, from astronomical to subatomic. Despite all this functionality, the API is still straightforward to use. The details of rendering are handled automatically. By taking advantage of Java threads, the Java 3D renderer is capable of rendering in parallel. The renderer can also automatically optimize for improved rendering performance. A Java 3D program creates instances of Java 3D objects and places them into a scene graph data structure. The scene graph is an arrangement of 3D objects in a tree structure that completely specifies the content of a virtual universe, and how it is to be rendered. Java 3D programs can be written to run as standalone applications, as applets in browsers which have been extended to support Java 3D, or both.“ [Sun, 2000].

As described in the definition of the Java 3D API the primary advantage is the high level aspect of the library. The programmer does not have to deal with the low level concepts such as the drawing itself, output device handling, parallelisation etc., and is therefore free to concentrate on the content of the 3D representation itself. Instead of rendering the objects directly like in low level OpenGL the objects are represented in a tree like data structure which allows various optimisations before rendering and easy interaction/modification with individual objects. *Fel! Hittar inte referenskälla.* shows a simple example of a scene graph in Java 3D. The figure describes the minimal scene graph necessary to display a shape, using the generic three-dimensional representation of objects in Java 3D.
In this paragraph the design and current implementation of the Advanced Visualisation Component will be explained briefly. In order to develop a visualisation component for an integrated system, a default development process has to be customised. DFKI decided together with the technical partners of the SUDPLAN consortium that it would save time and thus more cost efficient to develop the visualisation component in a sand box. A sand box, in this context, is a small executable application delivering a lightweight environment for testing the visualisation component independently. This procedure has the advantage that the complete SMS does not have to be started in order to test the features of the visualisation component. Consequently, in order to guarantee a nearly seamless integration the commonly known facade pattern [Gamma, 2005] is used to enable design by contract [Meyer, 1992] and thus to deliver an independent component. The overhead this approach produces will be compensated for by the benefit of a modular architecture, which is clearly defined through its interfaces and facilitates reuse of the developed components.

**Figure 56: Example of a Java 3D Scene Graph**

In this paragraph the design and current implementation of the Advanced Visualisation Component will be explained briefly. In order to develop a visualisation component for an integrated system, a default development process has to be customised. DFKI decided together with the technical partners of the SUDPLAN consortium that it would save time and thus more cost efficient to develop the visualisation component in a sand box. A sand box, in this context, is a small executable application delivering a lightweight environment for testing the visualisation component independently. This procedure has the advantage that the complete SMS does not have to be started in order to test the features of the visualisation component. Consequently, in order to guarantee a nearly seamless integration the commonly known facade pattern [Gamma, 2005] is used to enable design by contract [Meyer, 1992] and thus to deliver an independent component. The overhead this approach produces will be compensated for by the benefit of a modular architecture, which is clearly defined through its interfaces and facilitates reuse of the developed components.

**Figure 57: Advanced Visualisation Component Building Blocks** shows the core building blocks of the visualisation component, which will be explained in detail on a technical level in the following sections. Core classes of the single components will be presented in standard Unified Modelling Language (UML) Class Diagrams [Booch, 2005] combined with simple tables describing the single classes in order to advance comprehension. The classes are reduced to the important methods and attributes in order to lay special emphasis on the important parts. The description of the renderer is left out intentionally because the Java 3D rendering engine is used as described in 4.3.1 - Components and APIs used.
4.3.2.1 Layer

The concept of a Layer is ubiquitous in the visualisation component. All content is added to the visualisation component in the form of layers. A layer encapsulates information and meta information about the content which should be displayed. For example, a layer ‘knows’ which content it provides, e.g. elevation data, buildings, textures etc. There are more layers available than represented in Table 1: Core Layer Classes in order to simplify the overview. A more complete list may be found in the source code and developer documentation referred to in Fel! Hittar inte referenskälla. - Fel! Hittar inte referenskälla.. Figure 58: Layer Class Hierarchy presents the layer management classes.
Figure 58: Layer Class Hierarchy
The `Layer` class is the base class for all layers and defines the basic operations for controlling attributes such as name, icons, visibility, geospatial extend etc.

The `AbstractLayer` implements most of this functionality in order to provide a base class for all more specific layer classes.

Specialisation of `AbstractLayer` which can handle files conveniently. Similar as the `AbstractLayer` class this class serves as a base class for other concrete implementation.

`ElevationLayer` for handling digital elevation models and to control the texturing of the same.

`GeographicImageLayer` `Layer` for handling geospatial referenced images (e.g. Geo Tiffs) and to display them on top of elevation data.

Table 1: Core Layer Classes
Figure 60: Layer Management Classes

### Class

**LayerManager**

The `LayerManager` interface defines methods providing the means to handle layers. Layers will be added and removed through the `LayerManager`. The `LayerManager` also notifies registered listeners about layer state events.

**SimpleLayerManager**

A ready to use implementation of the `LayerManager`

**LayerListener**

Combines `LayerState` notifications e.g. layer added/removed with `PropertyChangeEvent`

Table 2: Layer Management Classes

#### 4.3.2.2 Camera

In order to create a picture of the interactive 3D scene a camera model is used to control the positioning of the user view in the virtual world. Camera management gives developers the ability to position and query the view of the visualisation scene. A geographical adapter allows the use of the camera directly with geographical units instead of the internal coordinate system. The camera listener mechanism, combined with the calculated 2D view bounding boxes, can be used to synchronise the Advanced Visualisation Component with other components, such as a cadastral map or a Satellite Map.
Class | Description
-----|---------------------
**Camera** | The *Camera* is the base interface for all camera operation. It provides methods for setting and retrieving the camera position and direction. It also provides convenient methods for setting the camera to look at a specific point in the scene. It also provides access to orientations vectors (up, down, left, right). It defines methods for calculating the view bounding box, which is the visible part of the surface.

**SimpleCamera** | An implementation of the above specified camera.

**GeographicCameraAdapter** | Encapsulates a *Camera* object and performs the transformation from geographic coordinates e.g. WGS 84 to the internal coordinates used by the visualisation component and vice versa. This allows direct interaction between the visualisation Component and GIS.

**CameraListener** | Delivers *CameraEvents* to registered listeners about camera updates. See *CameraEvent*

**CameraEvent** | The event containing *Camera* changes such as position and view direction changes.

Table 3: Core Camera Classes
4.3.2.3 Input and Output (IO)

The IO component is mainly used as a support library to transform input files into data types more appropriate for visualisation purposes. The IO component creates Layer objects out of well known spatial data types such as Shape files, ESRI ASCII grids, etc. There are more loaders available than represented in Table 4: Core IO Classes in order to simplify the overview. A more complete list may be found in the source code and developer documentation.

![Figure 62: Loader Classes](image)

<table>
<thead>
<tr>

<td>Implements basic functionality to handle files either in the host system or via unified resource locator (URI)</td>
</tr>
<tr>
<td>SceneLoader</td>
<td>A Java 3D based loader which creates a Java 3D scene object, a data structure representing a scene graph for representing 3D content.</td>
</tr>
</tbody>
</table>
AbstractSceneLoader | Partially implementation of a SceneLoader.
ElevationLoader | The ElevationLoader parses a digital elevation model from the specified files. Currently ESRI ASCII grids are supported.
Shapeloader | The ShapeLoader processes ESRI Shapefiles. Currently only lines and polygons are supported.
IOUtils | Convenience class for creating Layer objects directly without having to use or know about the loader hierarchy directly.

Table 4: Core IO Classes

4.3.2.4 Rendering

The rendering component is responsible for producing pictures from the available layers. These pictures will be the final visualisation the user will perceive. The complete rendering is done in the first version by the Java 3D API as described in 4.3.1 - Components and APIs used.

4.3.3 Second Year Development

As already stated in 4.3.2 Fel! Hittar inte referenskälla. it was necessary to make a switch in the components used. In the beginning of the second year it became evident that it would not be possible to provide all the needed features – like generating terrain from elevation models, selecting and displaying images from imagery servers, automatic caching and tiling, etc. – within the project scope if it must be built from scratch. The initial decision to use Java3D as a basis of development was reviewed and possible solutions were discussed with the technical partners within SUDPLAN.

The plan for the second year of the development, as described in the previous version of this document, was to

- Implement a Virtual Globe metaphor for visualisation
- Support more Digital Elevation Models
- Support the use of standard geospatial services such as WFS/WMS
- Enhance integration/visualisation of pilot specific data and adequate visualisation metaphors
- Improve navigation and user experience of the first version
- Further improve the infrastructure of the Advanced Visualisation Component

Reviewing the initial possibilities of the first year under the constraints of seamless integration into the SMS it became clear that the World Wind Java SDK would be the best match for further development of the Advanced Visualisation Component, as it already provides a Virtual Globe metaphor, improved navigation capabilities compared to the year one prototype and support for basic geospatial services.

It was decided to use the World Wind Java SDK component as a basis for all further developments of the Advanced Visualisation Component, because it is available as open source, delivers a lot of features needed within the project and has the smallest overhead when integrating it into the SMS.
Furthermore, the virtual globe provided by the World Wind Java SDK already provides some of the aforementioned features planned for the second year, thus we could focus the development on the remaining features and the integration of pilot specific data/results.

Because of the above mentioned decision – to switch to the World Wind Java SDK – the first task was to implement and integrate the new version using World Wind into the SMS that provides the same set of basic features as V1. Since the implementation of the basic feature set could be completed quite quickly, we were able to focus on special visualization tasks. In addition, the integration of input data from the pilots was performed as data became available.

Figure 63: Features provided by the World Wind Java SDK (blue)

Figure 64: 3D Visualization Component Using World Wind Java SDK
Figure 65: 3D Visualisation of Air Quality and Traffic Density in Stockholm

Figure 65 illustrates the relation of air quality and traffic in the city of Stockholm. Since the World Wind SDK already provides many standard GIS features (e.g. elevation model, compass, the possibility to increase the digital elevation model etc.) the 3D visualization is able to focus on suitable visualization techniques.

4.3.3.1 Integration of the World Wind SDK

The integration of the World Wind SDK into the Advanced Visualisation Component and thus into the Scenario Management System was the first task that had to be completed. In order to achieve this, different interfaces of SUDPLAN’s 3D visualization component had to be enhanced.

First, the interface VisualizationComponent with its implementation VisualizationPanel has been changed (see Figure 66). The class LayerAction is an event type to provide the mean for the Scenario Management System to turn on / off a selected Layer in the 3D visualization component. Moreover, we added methods to add and remove a layer. The input for this method is of type Object to be able to support an unlimited number of possible data sources. Which kinds of data sources are being supported depends on the implementation. Currently, the only implementation of the interface VisualizationComponent is the class VisualizationPanel. This class supports data sources of type File, URI, and URL to be able to support local as well as any remote data source (e.g. web services, etc.).
Figure 66: Class LayerAction

Considering the integration and usage of the World Wind SDK the interface definition for the VisualizationComponent and its implementation VisualizationPanel had to be changed slightly. The class LayerAction provides the means to disable/enable different layers shown by the 3D visualization component. As in the former implementation the synchronization of the 2D map view with the 3D virtual globe view and vice versa was a challenging task. In order to address this problem the methods add/removeCameraListener(), get/setCamera(), and get/setBoundingVolume() have been added to the VisualizationComponent.

Figure 67: CameraListener
The CameraListener is derived from the java.beans.PropertyChangeListener. Every change of the camera position is sent to the classes implementing this interface. While add/removeCameraListener() ensures that any change of the camera position or orientation within the 3D visualization is also displayed in the 2D view the methods get/setCamera() and get/setBoundingVolume() ensure that any change in the 2D view is also visible in the 3D component. The former one uses a kind of an observer pattern. In order to get any changes from the 3D component the “surrounding” Scenario Management System only needs to implement the interface CameraListener (see Figure 68).

The interface Camera (see Figure 69) is the interface for the camera operations in the 3D visualisation component and serves as a data structure. It provides methods for retrieving the camera position (latitude and longitude), the viewing direction, and the BoundingVolume (see Figure 68). Using the class SimpleCamera the user is able to define the position and orientation of the camera and thus the view onto the virtual globe. Here, the view immediately switches from one position to another without any animation. In contrast to the SimpleCamera class the AnimatedCamera class provides a mean to animate the camera view in a flight mode to a new camera position.

Figure 68: Animated Camera and BoundingBox

The Camera provides an interface for a data structure used to control the camera position and orientation. Using the class AnimatedCamera one is able to animate the camera on an interpolated path to a desired position in a flight mode. The class BoundingBox covers a geographic area.
Finally, the methods `setBoundingVolume()` and `getBoundingVolume()` provide a means to set or get the camera position – and move it to the correct position – according to the area covered by the BoundingVolume. Currently, the only implementation is the class `BoundingBox` with its private attribute `sector`. This object member is defined by four corners (see Figure 68). Later, any other BoundingVolume could be added to support different kinds of primitives or geometric volumes (e.g. bounding sphere, etc.).

### 4.3.3.2 The Visualization Wizard (VisWiz)

Because of many features already provided by World Wind’s virtual globe we were able to come up with a more general concept in order to cope with the pilots’ visualisation needs. We developed a new visualisation wizard called VisWiz (see Figure 69). The idea of VisWiz is to provide a means to support the user in selecting a suitable and state-of-the-art visualization technique both in the sense of scientific visualization and information visualization.

![VisWiz Screenshot](image)

**Figure 69: VisWiz Screenshot**

Figure 69 depicts an example of the visualisation Wizard (VisWiz). With VisWiz the user is able to select between different visualization techniques for one or multiple attributes provided as input source.

The VisWiz was designed to support all user types for selecting suitable visualisation techniques for the selected data even if they are not familiar with visualisation in general or the content of the data source. In order to be usable for a wide variety of data sources and by a broad user group, great emphasis was put on the following points for the design of the VisWiz:

- **Independence from data source**: The user should be able to use data even if they are not in the SUDPLAN SMS (e.g. results produced by external sources)

- **Extendable visualisation collection**: It should be possible to easily extend the collection of visualisations with new techniques.

- **Intelligent proposal**: The system should be able to propose suitable visualisation techniques based on the selected data so the user does not need to have any prior knowledge.

- **Simple user interaction**: An inexperienced user should be able to use existing data sources to produce suitable visualisations without further knowledge of the data or visualisation techniques
Fel! Hittar inte referenskälla.

0 illustrates an abstract overview of the design and workflow of the VisWiz component. VisWiz is divided into several modules to allow for an easy extension of supported data formats/sources, suggestion functions as well as state-of-the-art visualisation techniques. Techniques in the area of scientific visualization and information visualization are of special interest.

**Figure 70: Abstract VisWiz Modules and Workflow**

Input module: The input module provides an easy interface to allow the user to choose a data source which should be used for the visualisation. This could be a result file from an external simulation tool, a result stored within the SUDPLAN SMS or an online resource (i.e. remote WFS server).

I/O module: The I/O module imports the selected data source into the internal data structure for the visualisation component which is based on the OGC Data Structure (Fel! Hittar inte referenskälla.), determines what feature and data types are included within the chosen data and interprets additional meta information which could be available. The I/O module computes an attribute vector describing the imported data (feature types, attribute types, meta data) in a way to automatically determine suitable visualisation techniques in the Decision module.

Pre-selector module (optional): If the user is familiar with the selected data or already knows which attributes they want to visualise they can select attributes of interest and thus constrain the attribute vector which is used to determine the possible visualisation techniques.
Visualisation Collection: The visualisation collection consists of all available visualisation techniques. Additional meta information for each technique, which is used by the decision module to determine if it is suitable for the selected data, is also include in the collection.

Decision module: Based on the attribute vector computed by the I/O module and the meta information from the Visualisation Collection the decision module determines a subset of visualisation techniques suitable for the selected data.

VisWiz UI: The VisWiz UI presents previews along with further information on the usage of the suitable visualisation techniques, e.g. minimum number of needed attributes, to the user. The user can select a visualisation technique and is then guided through the attribute selection for the different visualisation parameters.

![Figure 71: OGC Based SUDPLAN 3D Data Structure](image)

An example workflow is depicted in Figure 72. The user opens a data set and the VisWiz presents the suitable visualisation techniques. In this example, street level results for air quality were chosen by the user. As the features in the data set are LineStrings, the system proposes the visualisation techniques “Extruded PolyLine” and “PolyLine”. The user chose the “Extruded PolyLine” technique which needs two parameters, one for the height and one for the color of the generated polygon. The user is then presented a dialog where they can easily map attributes from the selected data source to the two parameters of the visualisation. In this example the user wants to use the attributes “Perc98h” (98 percentile for NO concentrations) and “NrVehTot” (total number of vehicles). In the example these two attributes are mapped to the ‘height’ and ‘color’ parameter of the visualisation (left) and vice versa (right). The result of the different combinations is shown at the bottom.
Figure 72: VisWiz workflow

Figure 72 shows an example for a VisWiz workflow. After the selection of the data source the user selects a visualization technique. Depending on their selection and the input parameters the user is able to map the attributes of the data source. According to the mapping of attributes to visualisation parameters different presentations will be computed.
4.3.4 Third Year Development

Based on the developments of the second development year, goals for the third year are:

- to implement further visualization techniques from the current state-of-the-art in information and scientific visualization, e.g. volume visualization techniques like marching cubes for isosurface generation. Here, we will especially focus on information visualization in combination with suitable interaction means.

- to integrate the visualisation techniques into the VisWiz to enable the user to change and test different types of visualisation in an easy way.

Moreover, the 3D visualization will take advantage of new display devices like 3D stereoscopic desktop screens as well as 3D stereoscopic projections. Finally, we will investigate how modern input devices like multi-touch devices support users in the context of a GIS environment.

4.3.5 Current Release Feature Summary

As described above the current release provides many new features because of the usage of the World Wind Java SDK (see 4.3.3.1), for example:

- Open-standard interfaces to GIS services and databases
- Capable to display high-resolution imagery, terrain, and geographic information from any open-standard public or private source
- Huge collection of high-resolution imagery and terrain from NASA servers
- Supports Coordinate System: Lat/Lon, UTM, MGRS
- Supports of GeoTIFF, JPG, PNG, and JPEG2000
- Supports standard GIS formats: Shape File, KML, GML, GeoJSON
- Different Navigation Modes are being supported
- Supports visualization for stereoscopic displays

With this we are able to open and display most of the data sets provided by the pilots (local results, city models, etc.) as well as results provided by the Common Services. Moreover, the current release provides the new toolkit VisWiz (see 4.3.3.2). Independent of the supported input source the user is capable of selecting between different 2D and 3D visualization techniques for the attributes of a data source (e.g. the user can select whether he wants to visualize height as color or as geometric primitive). VisWiz is also capable of providing the user with a selection of visualisation techniques suitable for the chosen data. This enables inexperienced users to easily compose visualizations of the data even without having prior knowledge about the included attributes.
Conclusions

This document accompanies the software deliverable *D3.2.2 Product Implementation V2*. In this report we presented the results of the second of three development cycles of WP3 *Scenario Management System* of the SUDPLAN project. In addition, we explain the relationship of the deliverable to other tasks and deliverables, and provide a justification for the choice of technologies and basic software products used in the context of the Scenario Management System development.

In contrast to *D3.3.2 Scenario Management System V2* which will present integrated software, this document focuses on the individual building blocks of the scenario management system. The software presented here is used to implement the four pilot applications, which is an ongoing activity.

The work in WP3 can be categorized according to three building blocks as:

a. **scenario management platform functionality** including model management, basic visualisation etc.

b. **model as a service integration** based on related OGC SWE standards and

c. **advanced visualisation** functionality including an interactive 3D Map component

For each building block information on the technical baseline is given. Moreover, the text includes a list of core features, the documentation of the main developments carried out as well as a brief outlook on the future development plans.

Regarding the individual building block development activities, the main achievements of the second year are:

- The design, development and integration of a Time Series Comparison Framework to support Scenario Comparison
- The design, development and integration of an enhanced Model Management (Asynchronous Model Execution Framework)
- Developments to support an enhanced Common Service integration and user interaction support
- The design, development and integration of a globe based 3D Component
- The design and development of a Visualisation Wizard to enable end users to choose individual visualisation metaphors.

A large part of WP3 work, the concrete Common Service integration activities as well as the documentation of the Integrated Scenario Management System functionality will be subject to *D3.3.2 Scenario Management System V2* (Companion Report).

# Annex 1: Glossary

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Climate scenario</td>
<td><em>Climate scenarios</em> means the resulting climate evolution over time, as simulated by global (GCMs) and regional (RCMs) climate models. Climate scenarios are products of certain emission scenarios that reflect different economic growth and emission mitigation agreements.</td>
</tr>
<tr>
<td>Common Services</td>
<td><em>Common Services</em> are the climate downscaling services for rainfall, river flooding and air quality, developed in the SUDPLAN project and accessed through the SUDPLAN platform (Scenario Management System).</td>
</tr>
<tr>
<td>Emission scenario</td>
<td>European cities will also handle different local <em>emission scenarios</em> (to the atmosphere) that to a large extent influence future air quality, but with little influence on global climate.</td>
</tr>
<tr>
<td>Information product</td>
<td>Raw data, such as the results of mathematical modelling, and the analysis thereof, will often need to be packaged in such a way as to be accessible to the various stakeholders of an analysis. The medium can be one of a wide variety, such as print, photo, video, slides, or web pages. The term <em>information product</em> refers to such an entity.</td>
</tr>
<tr>
<td>Model</td>
<td>A <em>model</em> is a simplified representation of a system, usually intended to facilitate analysis of the system through manipulation of the model. In the SUDPLAN context the term can be used to refer to mathematical models of processes or spatial models of geographical entities.</td>
</tr>
<tr>
<td>Profile</td>
<td>Within SUDPLAN a <em>profile</em> is a set of configuration parameters which are associated with an individual or group, and which are remembered in order to facilitate repeated use of the system.</td>
</tr>
<tr>
<td>Report</td>
<td>A <em>report</em> is a particular type of information product which is usually static and might integrate still images, static data representations, mathematical expressions, and narrative to communicate an analytical result to others.</td>
</tr>
<tr>
<td>Scenario</td>
<td>A <em>scenario</em> is a set of parameters, variables and other conditions which represent a hypothetical situation, and which can be analysed through the use of models in order to produce hypothetical outcomes.</td>
</tr>
<tr>
<td>Scenario Management System</td>
<td>Scenario Management System (SMS) is synonymous with SUDPLAN platform</td>
</tr>
<tr>
<td>---------------------------</td>
<td>---------------------------------------------------------------------</td>
</tr>
<tr>
<td>Scenario Management System Framework</td>
<td>The <em>Scenario Management System Framework</em> is the main Building Block of the Scenario Management System. It provides the Scenario Management System core functionalities and integration support for the other Building Blocks.</td>
</tr>
<tr>
<td>Scenario Management System Building Block</td>
<td>Scenario Management System Framework is composed of three distinct <em>Building Blocks</em>: The Scenario Management System Framework, the Model as a Service Building Block and the Advanced Visualisation Building Block.</td>
</tr>
<tr>
<td>SUDPLAN application</td>
<td>A <em>SUDPLAN application</em> is a decision support system crafted by using the SUDPLAN platform and integrating models, data, sensors, and other services to meet the requirements of the particular application.</td>
</tr>
<tr>
<td>SUDPLAN platform</td>
<td>The <em>SUDPLAN platform</em> is an ensemble of software components which support the development of SUDPLAN applications.</td>
</tr>
<tr>
<td>SUDPLAN system</td>
<td><em>SUDPLAN system</em> is synonymous with SUDPLAN application</td>
</tr>
<tr>
<td>User</td>
<td>The term <em>user</em> refers to people who have a more or less direct involvement with a system. Primary users are directly and frequently involved, while secondary users may interact with the system only occasionally or through an intermediary. Tertiary users may not interact with the system but have a direct interest in the performance of the system.</td>
</tr>
<tr>
<td>Web-based</td>
<td>Computer applications are said to be <em>web-based</em> if they rely on or take advantage of data and/or services which are accessible via the World Wide Web using the Internet.</td>
</tr>
